Montreal, Que., May 19, 1917.—The decision of the government to put into force some form of selective conscription has long been awaited with more or less interest, and now that the step has finally been taken, it remains to be seen what period of time will elapse before an actual start is made in the new plan of action. What effect this new development will eventually have upon the commercial and industrial activity of the country, is at present difficult to determine, but in the accomplishment of the purpose, it is anticipated that slight disorganization will be caused by the system of selection, as it will undoubtedly be necessary to have some sort of a readjustment of the man power of the country in order to meet the required conditions. The political situation in the States is slowly but surely becoming clearer, but definite information regarding the plans of the government are very vague. The market is still in a somewhat unsettled condition, but the general tendency is a stronger tone with a continued upward movement in price quotations. Production of the heavier types of shells is showing a falling off, but otherwise the activity of this district maintains a brisk and war-time appearance.

Pig Iron

The continued heavy demand for pig iron and the filled-up condition of the producers has again been reflected in higher prices on the American market, but orders are still being placed for first half of 1918 delivery, and with the new developments now in progress the requirements for pig iron will become greater. One dollar per ton has been added to the Pittsburgh quotation of Bessemer, the price being now $46.95 per ton. Composite pig has advanced over 75 cents during the week, the quotation being $42.735 per ton. Canadian producers have very little to sell and prices are practically withdrawn.

Steel

The steel situation is still featured by the developing plans of the American government, but full requirements for war purposes have not yet been definitely announced. The market consequently retains a certain degree of uncertainty, and producers are reluctant to take on heavy business for future delivery until they know the tonnage desired for government purposes. The knowledge acquired from the experience of the Allies during the past three years of war, will no doubt have great bearing in the method adopted in forming a policy for the further prosecution of the war, both as regards purchase and manufacture of every form of munitions and equipment. In addition to supplying the Allies with large quantities of war materials, the placing of an army in the field will require increased energy on the part of manufacturers in keeping up the flow of supplies, and under the circumstances it is more than likely that some domestic enterprise will require to be deferred until a later date. This latter phase of the country's activity has, however, shown considerable decline, owing to the abnormal conditions prevailing in the steel market and the exorbitant prices asked for all grades of steel and iron.

It is generally conceded that the price paid for government requirements will be closer to that prevailing in the open market than was the case in previous purchases. General demands upon producers are unchanged, being such that early delivery is almost impossible. Far future positions are the only ones available, with the exception of small surplus lots offered to old customers. An additonal $10 a ton has been placed on the Pittsburgh quotation of certain grades of unfinished steel; billets are now $95, sheet bars have attained the century mark, rolling billets are quoted at $90, while the general price for forging billets is $110 per ton. Pittsburgh producers have advanced steel bars $5 per ton, the base price being now 4c. per lb. Following an advance of $10 per ton, the base on black sheets is now 7½c. On a similar advance, tin mill black is quoted at the same figure. Blue annealed sheets are now 7c. and galvanized 9½c., the week's advance on the latter being $10 per ton. With the exception of the advance on plates, noted last week, the situation here remains the same, but dealers predict further readjustments in the near future.

Metals

The metal market is becoming more settled as the American political situation develops. Copper is again weakening after the recent upward movement. Tin is fluctuating as conflicting conditions are reported. The higher price of ore has kept spelter firm. Lead is very strong and higher and antimony is quiet, but firm. Aluminum is steady and unchanged.

Copper.—This market is still influenced by pending developments and the recent upward movement has been retarded with a slight decline in prices quoted. The trade is apparently awaiting the further action of U.S. government before entering the market for heavy future requirements. London is firm, but New York shows a weak tendency with a decline of ½c. on the week, the quotation for lake and electro being 32½c. per lb. The local market is firm and unchanged at 38½c. for lake and electrolytic, and 37½c. for castings.

Tin.—This metal is again reacting, and this week's quotation on the New York market, although higher than the corresponding day of last week, is lower than what it was during the interval. A peculiar condition exists in the tin situation, as many consumers who are oversupplied with metal could resell if not under government restriction. Until action is taken by the authorities, the tin market will continue to be unsettled. London is much higher and New York is still 1¼c. higher than last week, the spot price being 65½c. per lb. Local dealers are quoting 62½c., this being a decline on the week of one cent per lb.

Spelter.—The firmness in this metal is retained more as a result of the higher cost of production than any activity in the general market. New York prices are ⅛ lower than last week, while dealers were continue to quote 13½c. on a quiet market.

Lead.—This metal continues to be the feature of the market as it persistingly maintains its abnormal strength in spite of general uncertain conditions. The advance has been gradual but steady, the price having almost doubled in the past five months, opening the year at 5½c. on New York quotations with the present Trust price at 10c. per lb. The market here is very strong, this week's quotation of 13½c. representing an advance of ½c.

Antimony.—The market is easier for future positions, but prompt and early delivery is held firm at last week's quotation of 27c. per lb.

Aluminum is firm and unchanged at 70c per lb.

Machine Tools and Supplies

The decrease in the production of the larger sizes of shells has resulted in a considerable falling off in the machine tool activity, although some light business is still being done in the lighter lines of equipment for the smaller shells. The increasing requirements of shipbuilding is an encouraging feature of the situation, and while established plants in this district are utilizing their old equipment, increased inquiry is reported from other locations. Marine repair shops here are particularly busy and additions are being made to existing equipment. Demands for supplies and accessories are still very heavy, with the costs advancing to meet the higher expenditure necessary in the purchase of raw material.

Scrap.

The general tone of the scrap steel and old metal market is one of exceptional strength and activity. The continual advance of steel and the encouraging report of the metal situation continues to be a factor that assists in keeping scrap at a high level. The local situation is retaining its strength, but prices are unchanged with the exception of coppers, light having advanced one cent to 22c. per lb., and heavy grade to 26c., the latter having advanced ½c. per lb.

Toronto, Ont., May 22.—While the volume of trade continues satisfactory, the scarcity of raw and semi-finished materials is becoming a serious factor in the situation. Manufacturers are handicapped by their inability to procure the necessary materials for their plants, resulting in a curtailment of production. The coal situation is also causing considerable anxiety, as stocks are low, with prices still advancing. Dealers say that it is a question of supply and demand, and that there is no prospect of cheaper coal this year.

Steel

The situation in the steel trade is getting more complicated owing to the increasingly heavy demand and difficulty which the mills are having in filling orders. With the demand for steel so urgent and deliveries more backward than ever, a more serious shortage than already exists appears to be inevitable. This is especially true as regards ship plates and sections, but applies to practically all steel products. Canadian interests are constantly sending inquiries to the States for steel, but the mills there are so busy that it is very difficult to get the material even at the high prices now obtaining. A report from Buffalo states that a considerable inquiry has developed for bars from Canadian users. Some agencies have been advised by mills not to book orders, except on advice from the mills, until the Government needs have been ascertained. As practically the entire output of the Canadian mills is required for munitions and other war purposes, domestic consumers of steel for manufacturing and similar purposes have to get considerable material from the United States. This source of supply, however, is becoming daily more uncertain owing to the fact that Government requirements take precedence over all other business. As Government buying will undoubtedly be very heavy. the outlook is not very bright for manufacturers using iron or steel.

With such conditions prevailing, it is not surprising that prices continue to climb. There never was a time when supply and demand were so unequal. There is no improvement in the situation in sight, and the upward movement in prices will continue. Wrought pipe has again advanced, this time by $6 per ton, affecting both black and galvanized material. Boiler tubes, both seamless and lapwelded, have advanced. Many makers of iron and steel tubes are sold up for a year or more, and any mill that can make fairly prompt delivery can get heavy premiums over what are regarded as regular prices for forward delivery. The demand for ship plate is enormously heavy. According to leading authorities in the States, the entire output of ship plates for two years will be required for the Government shipbuilding programme. Sales of several thousand tons of ship plates have been made by Eastern mills at 10c Pittsburgh, while 10.40c was recently paid on 1,000 tons of hull plates by a Canadian interest. Prices of bolts and nuts have advanced.

The heavy demand for all grades of sheets continues, with the scarcity in supply for prompt shipment getting more acute. Many manufacturers have withdrawn from the market, and surplus tonnage has been absorbed by the Government. Prices continue very firm, particularly on blue annealed sheets, which have advanced 25c per 100 lbs. Higher prices on black, blue annealed, and galvanized sheets are expected at an early date.

The principal feature in the steel trade in the United States is the present and prospective Government buying. The Government needs are still indefinite, but are gradually assuming important proportions, particularly for steel plate for the proposed shipbuilding programme. Rolling schedules will likely be considerably disarranged to take care of Government requirements, and the output on this account will be affected. The shortage of cars is restricting the movement of steel from the mills and causing considerable delay to shipments of material to consumers. Prices of semi-finished steel are still advancing. Bessemer and O.H. billets, and O.H. sheet bars are now quoted at $85 Pittsburgh. Although $85 is quoted on sheet bars, this material has been sold at $95 for third-quarter shipments, and $100 has been paid for small tonnage for nearby shipment.

Pig Iron

The market continues active, with prices still advancing in the States. Local price for foundry pig iron is unchanged at $50, but an advance is expected any time. At Buffalo the price range now runs at about $46 to $47 for this year's delivery, although one producing interest is taking business at less than these figures. The furnaces are unable to furnish all the iron required by consumers, and deliveries are getting behind.

Scrap

While business continues dull, except in cast and steel scrap, there is a firmer undertone to the market and prices show indications of advancing. The high cost of pig iron is raising the value of scrap, while the increased demand is reducing supplies of this material. Prices of scrap lead are very firm, while copper and bars are also stronger.

Machine Tools

There is practically no change to note in the machine tool market. Business during the week has been rather quiet, although there have been a few inquiries received by local machinery houses for machine tools of a general description. Owing to a hitch in the preliminary arrangements, plans for the proposed shipbuilding plant in the Ashbridge's Bay district, Toronto, are held up. It is not definitely known yet if the work will be proceeded with. In the United States, considerable uncertainty surrounds the market for machine tools as the Government requirements are not yet known. Builders are holding back until the situation is clearer.

Supplies

Following an advance of 2c on pure Manilla rope, prices of transmission rope and drilling cables are higher. Manila rope is now 33½c, transmission rope 43½c, and drilling cables 38½c per lb. for ⅝ in., and larger basis. Packings are also up. Square braided is now 32c, No. 1 Italian 38c, No. 2 Italian 30c per lb. Putty has advanced 25c per 100 lbs., standard in 100 lb. drums being now $4.35.

Metals

The metal markets are much firmer, and the situation generally has improved. There have been no important price changes, quotations having been maintained at last week's levels. The copper situation is strong and higher prices appear likely. Business is being restricted pending a decision in regard to the American Government purchases, but as these requirements will be considerable, it is probable that prices will advance.

Copper.—The market continues dull and inactive, but quotations are holding firm with a tendency to advance. Little change in the situation in the market in New York is expected until Government business is finally decided. The opinion is generally held that the American Government and Allies will pay from 25c to 27c for their requirements and that the quantity involved will be very large. Local prices are unchanged and nominal, Lake and electrolytic being quoted as 37c, and castings copper at 36c per pound.

Tin.—The market continues strong and prices firm, with a higher tendency. The present upward movement in prices is due largely to a lack of transportation facilities, although some consumers fear a shortage of tin. Tin is quoted at 68c per pound.

Spelter.—Zinc ore recently advanced $7.50 per ton, which has tended to strengthen the spelter market, especially as future shipments are in good demand with a scarcity of offerings. The market is firm and quotations are unchanged at 12c per pound.

Lead.—The strength of the market is indicated in the "Trust" price of lead, which has advanced $10 a ton to the basis of 10c New York. The outside market is still higher, ranging from 10.50c to 10.75c, New York, for May and June shipments. In the meantime, lead is unchanged locally at 13.25c per pound.

Antimony.—There is a fairly good demand for antimony. The market is firm with some tendency to advance on offerings for earlier positions than July. In spot antimony the market is firm at 30c per pound.

Aluminum.—There is no change in the position of aluminum and the market is steady on the basis of previous quotations. Present price 68c per pound.

PORT ADVANTAGES OF VANCOUVER, B.C.

THE Secretary of the Vancouver Board of Trade has issued a notice to the effect that the people of British Columbia, and especially of the port of Vancouver, are anxious to promote closer relations with British shipowners. This matter has engaged the earnest attention of their Board of Trade, and at a recent meeting it was resolved to communicate with the leading shipowners in Great Britain with a view to securing, as far as possible, their co-operation. Their desire is to promote the policy of making Vancouver, which is the principal British port in the North Pacific, the headquarters of British shipping on that coast.

It is pointed out that the Dominion Government has just completed a large dock and grain elevator, and further extensive improvements and facilities are planned for shipping, including a large dry dock. The Vancouver Board of Trade has petitioned the Dominion Government to make the harbor of Vancouver a national free port. The harbor facilities will be found equal to any on the coast, but they do not, at this time, wish so much to suggest the exclusive advantages of Vancouver as a loading port as the advantages of establishing a branch office in Vancouver for the management and chartering of vessels engaged in Pacific Coast trade. If shipowners opened their own offices in Vancouver it would be an important help in developing the trade and resources of that Province by putting it more closely in touch with freighting facilities, and, at the same time, it is considered that it would not prejudice but facilitate trading from other ports on the coast.

The actual expense of opening an office in Vancouver, it is thought, would be offset by the greater efficiency of local control, and it is believed that a measure of decentralization would both promote the solidity of the Empire and the interests of British shipowners. Amongst the advantages put forth are: The proximity of the best bunker coal on the coast. The ability to co-operate with Canadian railroads, and to divert to this British port much traffic, which can be shipped to advantage by way of Vancouver to and from the Orient, including Asiatic Russia and Australia; the adequate facilities and low port charges of Vancouver.

BRITISH TRADE CORPORATION

HON. ALBERT STANLEY, President of the Board of Trade, stated in the House of Commons a few days ago, that the British Trade Corporation would have a capital of £10,000,000. It was proposed to raise £2,500,000, and it was necessary that one million should be subscribed before the prospectus was issued. He had interviewed representative bankers, he said, explained the scheme to them and asked their support.

The banks were practically unanimous in support of the scheme, although he could not say that all of them were equally enthusiastic in agreeing to subscribe capital. A number of the larger banks had subscribed towards the million which was necessary in order to launch the scheme. The Government did not propose to subscribe capital or subsidize the undertaking in any way. He believed the corporation would serve a very useful purpose.

STEEL MILL AND CENTRAL STATION

By K. A. Pauly.

A FACT, not generally appreciated, says K. A. Pauly in the *General Electric Review*, is that the power requirements of the large and even the moderate mills exceed those of any other industrial field of motor application. For example, the main rolls of the rail mill at Gary are driven by six induction motors having a combined rated capacity of 24,000 h.p., with a maximum momentary capacity of approximately 80,000 h.p., and the main rolls of the billet mill at the same works are driven by five motors with a combined capacity of 22,000 h.p. with a corresponding maximum momentary capacity. Then, too, we have the large reversing mills which are driven by motors from 2,000 h.p. to 7,000 h.p. taking peaks from 6,000 to 20,000 h.p. momentarily. In addition to the power taken by the main rolls there are a very large number of smaller motors scattered about the plant for driving all manner of auxiliaries required for unloading the ore and transferring it to the blast furnaces, driving the blast furnace auxiliaries, and for transferring the iron and steel from the time it is drawn from the furnace until it is shipped as finished shapes.

The station load diagram of a steel plant is the result of a combination of load curves of almost every conceivable shape ranging from the extremely intermittent cycles of the large motors driving single stands of rolls and the small motors operating the screw downs, lifting tables, etc., to the more or less constant loads of the larger motors driving multi-stand mills, blast furnace pumps, gas washers, etc. The load factor of a central station supplying a steel mill obviously varies with the magnitude of the plant, although that for small plants is higher than might at first be expected owing to the fact that most small works do most of their rolling in multi-stand mills, roll smaller sections, and take more passes to produce a given reduction. Further, the steel is of such length that it is looped in rolling and passes simultaneously through several stands of rolls, and in many mills several pieces are rolled at the same time, thus producing a much more uniform load than obtains with the large single stand mill.

When power is purchased at a rate which is dependent upon the peak demand as well as the energy consumed or where power is supplied from a comparatively small central station means can frequently be provided for reducing the fluctuations in the load, but as the method of accomplishing this result depends upon a variety of local conditions the various methods will not be discussed here.

Group Relation to Central Station

From the standpoint of the central station, steel mills can conveniently be divided into two groups. In the first are included those companies which operate their own blast furnaces, and in the second group those which purchase their steel in the form of ingots, billets, or slabs, etc., for rolling and fabricating works which purchase the rolled shapes. Although a few of those included in the first group do at present and probably will continue to purchase power to supplement that which is developed locally, the large majority of these companies have made and will continue to make all their own power as a by-product, and many have a surplus to sell. The following figures taken from a paper read before the A.I.E.E. in 1909 will serve to indicate the immense amount of energy available as a by-product incident to the manufacture of steel.

As a result of the reduction of the iron ore in the blast furnace there is produced in the form of so-called waste gases approximately 150,000 cu. ft. of gas having an average thermal value of approximately 90 B.t.u. per cu. ft. Of this approximately 30 per cent. is required for heating the hot blast stoves and approximately 25 per cent. for driving the blast furnace blowing engines, gas washing machinery and auxiliaries used in connection with the blast furnaces and blowing engines, leaving 45 per cent. or approximately 320 kw-hr. per ton of pig iron produced available for general power purposes. Also, many of the large steel plants are manufacturing the coke used in the blast furnaces which reduce the ore at the works and have available as a by-product of the coke ovens approximately 10,000 cu. ft. of gas having approximately 500 B.t.u. per cu. ft., of which approximately 50 per cent. or approximately 130 kw-hr. per ton of coke produced is available for general power purposes elsewhere in the mill. As very nearly a ton of coke is required to produce a ton of pig iron in the blast furnace, the by-product power available for general purposes from the blast furnace and coke oven gases is obviously approximately 450 kw-hr. per ton of pig iron. Also in many steel plants considerable additional power is being obtained from waste heat boilers used in connection with the open-hearth furnaces. While the power from this source is small compared with that from the blast furnace and coke oven gases, it is very considerable when compared with many industrial plants, and has an appreciable effect in lowering the cost of producing power in the large modern steel works.

Type of Equipment Installed

There seems to be a feeling inbred into the minds of steel mill men that 60-cycle equipment is not at all suited to steel mill conditions. The foundation for this is doubtless to be found in the fact that all or practically all of the large steel works throughout the country have adopted 25-cycle as the frequency of their power systems. This prejudice is frequently a serious handicap to the public service power solicitor who is trying to interest the steel company in his goods which he can offer only at 60 cycles. Many of the constant speed auxiliaries about the mill are driven by induction motors and with 60 cycles more speeds are available than with 25 cycles, there being seven speeds from which to choose within the range of 500-r.p.m. and above with the former frequency and only three with the latter. Also most of the equipment, such as motor generators, transformers, etc., are cheaper for 60 cycles and equally efficient and reliable. 25 cycles, however, has considerable advantage over 60 cycles for supplying the slow speed, direct connected, main roll motors, the power factor of such motors usually being higher for the same overload capacities and their costs less.

The difficulty of operating gas engine-driven generators at 60 cycles has also been an important factor in bringing about the adoption of 25 cycles by the large steel plants. There is, however, no fundamental reason why motors cannot be designed for 60 cycles to meet the severe rolling mill requirements, and any one of the large electrical manufacturers will readily guarantee such motors to develop the necessary overloads and to operate within any specified heating limits. The power-factor of the slow speed, 60-cycle machines is as previously stated lower than for 25-cycle units, but this defect can be neutralized by synchronous condensers. It is a fact, however, that most of the mills in the plants which fall in the second group are of the size and type which it is customary to drive either through gearing or rope transmission, thus permitting the use of motors of moderate speeds for which 60 cycles is at least as satisfactory, if not slightly preferable; so that in general it may be said that 25 cycles possesses little, if any, advantage over 60 cycles as a steel mill frequency for those plants which will consider purchasing their power.

Conclusions Drawn

As in the general treatment of all similar problems no definite recommendations can be made which will conform to all the special conditions which may surround any particular case. However, in summing up, the writer feels safe in drawing the following conclusions from his experience in this field of application of electric power. First, that if for reasons other than the question of frequency, the power for supplying the plant is to be developed locally, 25 cycles should be chosen as the operating frequency, except possibly in the case of some small plants referred to below. Second, that for plants falling in the second group, if reliable power can be purchased at a reasonable rate, which the writer believes is always the case, the mill frequency should be that of the available source of supply whether 25 or 60 cycles and the necessary power purchased, unless for reasons other than those having a direct bearing on the power problem, it is considered expedient to generate rather than purchase power. It is conceivable that it might be to the interest of the steel company to operate its own plant, although from power considerations alone this would seem unwise, and in such cases the adopted frequency should in general be the same as that of the local public service company so that in the event of a breakdown assistance can be obtained from the local company.

SENTINELS OF THE DEEP

By Capt. Geo. S. Laing

TO a great many people an island is a piece of land surrounded by water, but to those who "go down to the sea in ships," an island is an ocean oasis. This article will refer to lonely islands far removed from the main continents.

Island of St. Helena.

Is there at the present moment a sea-girt rock that has more historical value wrapped up in its precipitious cliffs than grand old St. Helena? Could one view a more inaccessible mountain-top rearing its bald iron pate above the South Atlantic Ocean? No thinking person could leave memories of this stronghold buried in the mind's vaults to rot. Inspiration simply radiates from such an island.

To fully appreciate the value of an island it is necessary to imagine that you are in the shoes of a shipwrecked sailor, naval strategist, or cable company director. These are a few of the men who circle round ocean islands lying maybe from 500 to 1,500 miles away from the next island or continent. St. Helena is situated in latitude 15° 55′ south, and longitude 5° 44′ west. The southeast Trade Winds blow over it all the year round and roughly it is 1,000 miles from the African coast and twice that distance from South America. If it were imperative for any native of St. Helena to change foot-stools, his nearest neighbor would be the island of Ascension some 700 miles to the northwest and nearer the Equator. Take St. Helena from a sailor's point of view first.

We are homeward bound from Java, India or Mauritius in a sailing ship and have come round the Cape of Good Hope. In some cases we may not have seen land for two months and suddenly a man from aloft hails the deck with the words, "land on the lee bow, sir." In the morning glory of the tropics, the island—still forty miles away—looks like a tiny rain squall kissing the ocean from a surrounding clear sky. To those who have never lost sight of dry land its presence is commonplace, but the sighting of this little ocean rock kindles a fire in the thoughts of seamen, just as an Atlantic passage in a palatial steamboat becomes a revelation to thousands of land folks.

St. Helena's Inhabitants

Our craft is sailing along at six or seven miles an hour, with yards a little canted to port. The rain squall effect soon takes on a definite outline and the island now resembles a gasometer. Towards afternoon our craft is sailing along under the very frown of the island cliffs and two or three native whale-boats are towing from our lee rail. Their shades in features denote that the peon classes of this island are drawn from more than one or two original clans of black and white. One pleasant thing to note is their clean overalls of blue cotton, for apparently the island people believe in soap and water having a big say in their lives.

They have fish, vegetables, fruits and curios for sale, and one man from each boat comes on board while the others remain to bend on to a rope what may be hauled on deck. If our voyage has been long, appreciation of fresh vegetables and fruits is great. The curios consist of ladies' wrist bangles made from elephant grass seed or shells, and chatelaines of the same materials. Perhaps the "best seller" is a booklet of blank paper with ferns, mosses and yellow daisies sewn between the leaves. As these plants have been grown on the ground surrounding Napoleon's grave, their value remains with one for ever, and stirs up many allied associations of land asd sea. As this is written, the writer is looking upon some dried ferns and moss that he brought from this historical rock in 1890, so age would appear to work slowly with such stuff.

We now open out the lee side of the island and can see the Ladder Hill. The stairway with its 700 steps is very plain and appears like a white-washed streak from sea to mountain top. There is an anchorage under the only town—Jamestown, but unless we had sickness on board, or had run short of drinking water we generally sailed right on towards the next peak—Ascension.

A Natural Fortified Island

St. Helena is heavily fortified by Nature as it has only one safe landing place and that is very limited. Its precipitous rise from the ocean, with the exception of this small shelf for anchorage water, makes it a most defiant place. Napoleon was as safe on this rock as far as escape was concerned as one could possibly be. All together this warrior lived seven years in his island prison, and his ashes rested in St. Helena for nearly twenty-one years before they were given to France for re-interment in Paris.

The native boats have gone their way, we have taken solar observations to check our chronometers, while old St. Helena dips into the ovean astern. Although the island can only receive a short innings in such an article as this, it should be said, that from the sea one can find no trace of flora, but those who know the rock from its hidden interior tell us that woods, pasturage and foliage abound behind its iron rock-bound cliffs.

Ascension Island

Ascension is another valuable island. In raising this island from the South, the conical shaped mountain of rock and sand looks as hot and blistered as the shores of Suez or Aden in their desert ovens. We generally signal the vessel's name and port of registry to the flag station on the slope of the peak. This island is invaded sometimes by "rollers" which are huge crestless waves, twenty to thirty feet in height, rolling inshore at a good velocity and breaking like wild cascades on the beach, these unwelcome ocean babies make anchorages unsafe; but again, an island's value is wrapped up in such things. As a cable station and a naval and military possession, our Empire could do with more such places. Their isolation and inacessability are gems when it comes to strategical movements, alike in commerce, war, and communication.

Sea turtles visit the shores of Ascension and paddle themselves aground; then with flippers dug into the sand these peculiar creatures crawl slowly to a point ten or twenty feet above high water mark. Here, instinct tells them to scoop out a hole two or three feet deep and deposit the eggs for old sol to hatch. As a layer, the turtle will take some beating, for one nest often contains 70, 80 or 100 eggs. The lady turtle only asks one quiet evening ashore to discharge her egg consignment, and as the sun is rising next morning she is launching her bath-tub body into the sea for another long trip in ballast.

This it is, that lonely rocks and islands in mid-ocean have a great value, although from a mineral or agricultural point of view they may be worthless. Bermuda and Sable island are our lonely islands in the North Atlantic, but whereever they may be, their value to a maritime nation is beyond reckoning.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the Commission headquarters are at Ottawa.

CATALOGUES

Buffing Machinery.—The Chase Turbine Mfg. Co., Orange, Mass., have issued a bulletin describing and illustratin describing and illustrating two styles of buffing and polishing machines. A specification is included covering the principal features.

Barker Chucks. — The Thomas Elevator Co., Chicago, Ill., have issued a binder containing six bulletins, A to F inclusive, dealing with various types of "Barker" chucks. Bulletin D describes a wrench operated chuck while the other bulletins deal with different types of wrenchless chucks. Each type is carefully described and its principal constructional features shown by means of sectional views and diagrams.

Tool Book No. 13.—The Goodell-Pratt Co., toolsmiths, of Greenfield, Mass., have published a new edition of their tool book. This complete pocket catalogue, which is a new issue, shows every article which the company manufacture and cancels all previous editions. It covers an extensive line of tools and devices for mechanics, artisans and amateurs, comprising altogether 432 pages. All the tools, etc., are illustrated and are also briefly described.

Enlarged Canadian Trade Intelligence Service

Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department of Trade and Commerce, Ottawa, is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.

BRAZIL—Bahia, British Consul. Rio de Janeiro, British Consul General.

CHILE — Valparaiso, British Consul General.

COLOMBIA — Bagota, British Consul General.

ECUADOR—Quito, British Consul General. Guayquil, British Consul.

EGYPT — Alexandria, British Consul General.

FRANCE—Havre, British Consul General. Marseilles, British Consul General.

INDIA—Calcutta, Director General of Commercial Intelligence.

ITALY—Genoa, British Consul General. Milan, British Consul.

MEXICO—Mexico, British Consul General.

NETHERLANDS—Amsterdam, British Consul.

PANAMA—Colon, British Consul. Panama, British Vice-Consul.

PERU—Lima, British Vice-Consul.

PORTUGAL—Lisbon, British Consul.

RUSSIA—Moscow, British Consul General. Petrograd, British Consul, Vladivostock, British Consul. Odessa, British Consul General.

SPAIN—Barcelona, British Consul General. Madrid, British Consul.

SWEDEN—Stockholm, British Consul.

SWITZERLAND—Geneva, British Consul.

URUGUAY—Monte Video, British Vice-Consul.

VENEZUELA — Caracas, British Vice-Consul.

Canadian Commercial Intelligence Service

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

CANADIAN TRADE COMMISSIONERS.

ARGENTINE REPUBLIC—B. S. Webb, Acting Canadian Trade Commissioner, Reconquista, No. 46, Buenos Aires. Cable address, Canadian.

AUSTRALIA—D. H. Ross, Stock Exchange Building, Melbourne. Cable address, Canadian.

BRITISH WEST INDIES—E. H. S. Flood, Bridgetown, Barbadoes, agent also for the Bermudas and British Guiana. Cable address, Canadian.

CHINA—J. W. Ross, 13 Nanking Road, Shanghai. Cable address, Cancoma.

CUBA—A. T. Quilez, Acting Canadian Trade Commissioner, Lonja del Commerci, Apartado 1290, Havana. Cable address, Cantracom.

FRANCE—Phillipe Roy, Commissioner General, 17 and 19 Boulevard des Capucines, Paris. Cable address, Stadacona.

JAPAN—E. F. Crowe, Acting Canadian Trade Commissioner, P. O. Box 109, Yokohama. Cable address, Canadian.

HOLLAND—P. H. Geleerd, Acting Canadian Trade Commissioner, Zuidblaak, 26, Rotterdam. Cable address, Watermill.

RUSSIA—C. F. Just, Canadian Government Commercial Agent, Alexandrinskaia, Plosch 9, Petrograd. L. D. Wilgress, Canadian Government Commercial Agent, Bukhgolza Ulitza No. 4, Omsk, Siberia.

NEWFOUNDLAND—W. B. Nicholson, Bank of Montreal Building, Water Street, St. John's. Cable address, Canadian.

NEW ZEALAND—W. A. Beddoe, Union Buildings, Customs Street, Auckland. Cable address, Canadian.

SOUTH AFRICA—W. J. Egan, Norwich Union Buildings, Cape Town. Cable address, Cantracom.

UNITED KINGDOM—Harrison Watson, Sub-division E.C., 2, 73 Basinghall Street, London, E.C., England. Cable address, Sleighing, London. N. D. Johnston, Sun Building, Clare Street, Bristol. Cable address, Canadian. J. E. Ray, Central House, Birmingham. Cable address, Canadian. J. Forsyth Smith, 31 North John Street, Liverpool. Cable address, Cantracom. F. A. C. Bickerdike, 4 St. Ann's Square, Manchester. Cable address, Cantracom. J. Forsyth Smith, Acting Canadian Trade Commissioner, 87 Union Street, Glasgow, Scotland. Cable address, Contracom.

CANADIAN COMMERCIAL AGENTS

AUSTRALIA—B. Millin, Royal Exchange Building, Sydney, N.S.W.

BRITISH WEST INDIES—Edgar Tripp, Port of Spain, Trinidad. Cable address, Canadian. R. H. Curry, Nassau, Bahamas.

NORWAY AND DENMARK—C. E. Sontum Grubbegd No. 4, Christiania, Norway. Cable address, Sontums.

SPAIN—J. F. Roberts, Care British Consulate General, Barcelona.

CANADIAN HIGH COMMISSIONER'S OFFICE

UNITED KINGDOM—W. L. Griffith, Secretary, 17 Victoria Street, London, S.W., England. Cable address, Dominion, London.

Duriron, a non-corrosive metal, is the subject of Bulletin No. 100, recently issued by the Duriron Castings Co., Dayton, Ohio. The bulletin first describes the chemical and physical properties of "Durion," which is of acid, alkali, and rust proof metal. The succeeding pages contain illustrations and descriptive matter covering "Duriron" standard pipe, drainage pipe, fittings, valves, cocks, pumps, blowers, etc. The concluding pages show illustrations of miscellaneous equipment such as tanks, condensers, stills and kettles, etc.

BOOK REVIEW

Jane's Fighting Ships, 1916, by the late Fred T. Jane, 449 pages, 12 x 7½ in. Published by Sampson Low, Marston & Co., London, England, price $5.25. This well known encyclopedia of the navies of the world is now in its nineteenth year of issue. This edition is new and complete, and has been sanctioned by the British Admiralty. In this edition the details of the British Navy have been reinstated, but without photographs and illustrations, and omitting, of course, any feature that might be of assistance to the enemy. The changes in this issue are suggestions of the late Mr. Jane, and have been carried out under the direction of Maurice Prendergast. A large number of new illustrations in the form of photographs, plans and silhouettes have been added, while many new maps of ports and harbors, brought into prominence by the war, have been included. Sections devoted to various navies have been enlarged and generally improved, while some very useful information has been included on German submarines. In spite of the restrictions imposed by the war, the book contains a great deal of valuable and interesting information. In regard to the British ships, although the illustrations and silhouettes have of necessity been omitted, particulars covering armament, machinery and general features are included. A list of illustrations of ships of all nationalities lost in the war is contained in the opening pages. The book has a list of contents and a general index, the latter being a list of ships of all navies. Additional to the 449 pages of reading matter are 161 pages of advertisements forming useful directory of shipbuilders and manufacturers. The book is printed on coated paper and bound in substantial cardboard covers.

Seventeen men were waiting in line at a ticket window in a railway station when an excessively inebriated person thrust himself at the head of the line and shoved thirty-five cents before the ticket agent.

"Gimme ticket f' New York," he said.

"You can't go to New York on thirty-five cents," answered the agent.

The exhilarated man wavered a moment, and then was struck with a brilliant idea.

"Say," he asked, "where can I go for thirty-five cents?"

And seventeen men told him.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

ENGINEERING

Thorold, Ont.—The Exolon Co., manufacturers of artificial abrasives, contemplate adding another unit to their plant here.

Toronto, Ont.—The Etobicoke Township Council propose to build an electric light plant to supply current to the district.

Bridgeburg, Ont.—A firm of motor truck manufacturers of Brazil, Ind., is contemplating locating a branch factory here.

Bala, Ont.—The Bala Electric Light & Power Co. will build a power plant. Grant & Thorpe, of Peterborough, are the general contractors.

London, Ont.—Steel Lockers, Ltd., a concern recently incorporated, plan to build a factory here for making metal lockers and furniture, etc.

Orillia, Ont.—The Inland Construction Co., are making fair progress with the new power development at Swift Rapids. The first of the three 1500 k.w. generators has been delivered.

St. Catherines, Ont. — A by-law has been passed by the City Council to sell a site to the Turnbull Electro-Metals, Ltd., for factory purposes. The sale is subject to the erection of a plant within two years.

St. Thomas, Ont. — The Dominion Brakeshoe & Foundry Co., whose plant is being finished expects to commence operations within the next thre weeks. The local branch is the first foundry of the American Brakeshoe Co. to be started in Canada.

Vancouver, B.C.—Plans for the construction of a $10,000,000 iron and steel plant in the vicinity of Vancouver are being made by a group of financiers according to a letter submitted to the City Council recently by Industrial Commissioner J. R. Davison.

Regina, Sask.—According to information received here, the Federal Governments will expend $300,000 in developing the lignite fields of Saskatchewan at Estevan. The development of those fields will solve the fuel question of this Province, it is believed, and prevent coal famines that have caused as much inconvenience during the past few winters.

MUNICIPAL

Tillbury, Ont.—The Town Council contemplate installing a pumping plant. Engineer, J. J. Newman, Windsor, Ont.

New Liskeard, Ont.—A by-law to raise $6,000 for the sinking of three new wells has been passed by the Council.

Trail, B.C.—The City Council propose spending $80,000 for extensions to the waterworks plant. A by-law will be voted on.

Hespeler, Ont.—A by-law to raise $14,000, to provide for extensions to the waterworks system, has been passed by the ratepayers.

Elmira, Ont.—It is proposed to grant a loan of $15,000 to the Elmira Machinery & Transmission Co., who will build an extension to their factory.

Davidson, Sask.—The Town Council propose purchasing a power plant and making improvements to same. The total cost is estimated at $4,300.

Oshawa, Ont.—The Board of Works have submitted their report recommending the purchase of a new sprinkling wagon at a cost not to exceed $425.

Oshawa, Ont.—A proposal has been laid before the Council that a bonus to the extent of $15,000 be given to the W. T. Trick Co., and the assessment fixed at $10,000.

Ford, Ont.—A by-law will be voted on by the ratepayers to grant exemption from taxation to the Chalmers Motor Co., who are rebuilding their plant which was recently damaged by fire.

Port Dover, Ont.—A water works system and sewage system are being considered for Port Dover, the approximate cost being put at $65,000. It is likely that a by-law will be submitted to the people in August next.

Smiths Falls, Ont.—G. F. Drewery, one of the Hydro engineers, is in Smiths Falls to investigate the two local electric plants and to make an estimate of what it would cost the town to buy them. This, he says, is the first step in getting hydro electric power for Smiths Falls, and he will report to Council as soon as he completes his inspection of the plants.

Windsor, Ont. — Mayor Tuson, of Windsor, at a meeting of the Essex Border Utitlities Commission, held on May 18, expressed himself as strongly opposed to Morris Knowles, consulting engineer for the commission, being allowed to go ahead with plans for a temporary sewage system to serve Windsor and other border municipalities, including Ojibway, until the scheme had received the approval of ratepayers of each municipality.

Tillsonburg, Ont.—The ratepayers of the town defeated two industrial propositions at the polls on May 15, both failing to get the two-thirds necessary vote. The Tillsonburg Foundry & Machine Co. asked for a loan of $10,000 for five years at five per cent., a free site and a fixed assessment of $2,000 and agreed to employ 30 to 50 hands. The Canadian Cereal & Flour Mills sought a fixed asessment on their mills here of $30,000 and agreed to employ 30 to 50 hands in the oatmeal and pea mills for a period of five years.

GENERAL

Montreal, Que.—The Eureka Toy Co., Maisonneuve, Que., is preparing to build a factory to cost $85,000.

Montreal, Que.—The Hamilton Cement Co., in which Claude Bordier, Montreal, is interested, will build a plant at Point aux Trembles, Que., for the manufacture of cement, cement products, etc.

Markham, Ont.—The Markham Woolen Mills were struck by lightning and destroyed by fire on Saturday. The damage to building and machinery, etc., is estimated at $100,000, which is partially covered by insurance.

Kincardine, Ont.—The Watson by-law carried here by a majority of 41 over the necessary three-fifths. The people have, by their vote, decided to loan J. B. Watson $20,000 to assist in the establishing of another furniture factory here.

Galt, Ont.—This city has another new concern, the Galt Building Products, Ltd., which will manufacture, by a patent process, sand brick tile, artificial marble and other building materials. The company has secured eight acres of land, and expects to commence filling orders by June 1. The new industry has a provincial charter, and is capitalized at $40,000. E. S. Tolmie is the president.

CONTRACTS

Winnipeg, Man.—The Deputy Minister of Public Works has let a contract to the Canadian Westinghouse Co., for motor generator sets, at $28,360.

Wolseley, Sask.—The Town Council have awarded a contract for a generator and exciter to the Canadian Westinghouse Co., of Hamilton.

Toronto, Ont.—The Standard Chemical Co. have awarded a contract for 1,500 gallon per minute duplex pump to the Bawden Pump Co., Toronto.

Hamilton, Ont.—The Canadian Engineering & Construction Co., Hamilton, have been given the general contract for a $75,000 factory for the National Abrasive Co., of Boston, Mass.

Winnipeg, Man.—The Provincial Government has awarded the contract for the supplying of motor generators for the central power house, to the Canadian Westinghouse, Co. The contract price is $28,360. The Northern Electric Co. was awarded the contract for the lead covered cable and pot heads at a price of $10,000. The apparatus will generate and conduct power from the central power house, behind the new law courts, to the new Parliament Buildings and the Law Courts Building.

PERSONAL

W. C. Kennedy, president of the Windsor Gas Co., Windsor, Ont., has resigned in favor of **T. P. Pinckard.**

C. U. Peeling, of Oshawa, Ont., has been appointed manager of the Cornwall Street Railway, Light and Power Co., and the Stormont Electric Light and Power Co., in succession to Wm. Hodge, who has tendered his resignation after twelve years service.

C. L. Leighty, now inspector of transportation for Eastern Lines, with headquarters at Montreal, has been appointed superintendent of Canadian Pacific Telegraphs, Ontario Division, with headquarters at Toronto, vice **H. J. Lillie**, who has been assigned to other duties.

M. J. Butler, managing director of Armstrong Whitworth Ltd., Montreal and **D. A. McDougall**, general manager of the Dominion Steel Corporation Sidney, N.S. have had conferred upon them the honorary degree of L.L.D., at St. Francois Xavier University, Antigonish, N.S.

F. P. Gutelius, general manager of the Intercolonial Railway, had been offered the vice-presidency of the Delaware & Hudson Railway. Mr. Gutelius before joining the Intercolonial, was for many years a general officer in the engineering and operating departments of the C.P.R.

Almond Penfield Turner, formerly president of the Canadian Copper Co., a subsidiary of the International Nickel Co., died last Friday in Oakville, Ont., at the age of fifty-two, from Bright's disease. The late Mr. Turner spent most of his life in Cleveland, but was in Copper Cliff, Ont., for ten years, with the Canadian Copper Co., joining the company in a junior position and rising to the presidency. He retired five years ago on account of ill-health.

BUILDING

Montreal, Que.—Tenders for the proposed new Maisonneuve School for Boys on Pie IX. avenue, have been opened and the construction of four new schools to comprise 46 classes authorized at the regular meeting of the Catholic School Commission. C. A. Reeves, architect.

Winnipeg, Man.—City Building Inspector Rodgers has submitted plans for a proposed extension of King Edward Municipal Hospital to the Board of Control. He estimates the cost, including certain alterations to the present structure, at $22,589. Council will be recommended to order the work proceeded with.

MARINE

Vancouver, B.C.—A contract for the first ship to be built on the North Arm of the Fraser River has been signed by Messrs. Harrison & Lamond, contractors, and the Dominion Government, and calls for a wooden ship 225 feet long and 44 feet beam. It will cost $225,000.

St. John, N.B.—Thomas V. S. Dickson, of Glasgow, Scotland, representing a Clyde shipbuilding firm, and A. D. Swan, of Montreal, have been in St. John and Halifax recently, looking over the ground to ascertain the possibilities of establishing a shipbuilding plant.

Vancouver, B.C.—For the purpose of having her coal-burning system changed to handle fuel oil, the steamer Quadra, formerly a Government lighthouse tender, but now owned by a Howe Sound mining concern, is at Vancouver. The alterations will be made by the North Shore Iron Works.

Sault Ste. Marie, Ont.—The Canadian freighter, W. Grant Morden, which went ashore Friday morning, was released on Sunday by the tug Manistique and passed down on her way to Lake Erie. She is undamaged. Downbound steamers report that ice field extends out into Lake Superior for a distance of 75 miles from Parisian Island. Boats are recommended to keep to the north passage.

Vancouver, B.C. The steel steamer War Dog, the first ship of its type to be built in British Columbia, was launched at the Wallace Shipyard on May 17. The War Dog, with a length of 315 feet, 45 feet beam, and a depth of 27 feet, is the first steel cargo vessel to be built in this province, and the contract was placed by a Japanese steamship company through an English firm. Since the steamer has taken to the water she has been sold to a British firm of Liverpool, believed to be the Cunards.

St. Clair Ship Canal Approved.—Word has been received in Sarnia that the International Joint Commission in session at Detroit have approved the proposed ship canal through the St. Clair River opposite this port, all objections on the part of the Canadian officials having been satisfactorily met. The Canadian and American engineers were instructed to begin work on the project at once, and the estimated cost is $92,000. The channel will be dredged from the mouth of the Black River to the St. Clair River tunnel, and will be used by upbound steamers.

Victoria, B.C.—The Drummond Lighterage Co., of Seattle, which recently sold the big car barge to the C.P.R. Co., has awarded contracts for two 800-ton scows to William F. Sehrs, shipbuilders, of Port Hadlock. The vessels are to be 120 feet long with a beam of forty feet and a depth of ten feet. With their completion, the Drummond company will have a total of eighteen scows in operation in the Puget Sound-British Columbia freighting business, the eighteen having a combined tonnage of nearly 10,000 tons.

New Westminster, B.C.—Wooden ships to the value of approximately one million dollars will be constructed at New Westminster and at other points along the Fraser River according to a contract just let by the Dominion Government. The allotment of the contracts will not be completed until after the Dominion Shipbuilding Commission for British Columbia reaches the Pacific Coast. It is understood that if satisfactory terms are arranged at least two and possibly more ships will be built in New Westminster shipyards. The yards at Coquitlam on the Pitt River will also probably be enlarged and used in connection with this ship construction programme as well as at Eburne and other down-river points.

INCORPORATIONS

The British American Rubber Co., has been incorporated at Ottawa, with a capital of $250,000, to manufacture rubber goods and supplies. Head office is at Toronto and the incorporators are Gordon E. Kellar, Edward J. Swift, and R. T. Grimshaw, all of Toronto.

Electrical Appliances, Ltd., has been incorporated at Ottawa with a capital of $50,000, to manufacture electric stoves, heaters, and appliances of all kinds at Hamilton. The incorporators are John F. Radigan, G. G. Sutherland, and Thos. D. Fallon, all of Hamilton, Ont.

The Canadian Flexible Skate Co., has been incorporated at Toronto, with a capital of $100,000, to manufacture a patent flexible skate at Parry Sound, Ont. The provisional directors are Carl L. Falstrem, John A. Bragg, and Henry Limbert, all of Parry Sound, Ont.

Reid Towing & Wrecking Co., has been incorporated at Ottawa, with a capital of $200,000, to carry on the business of towing, salving vessels. Head office is at Montreal, and the incorporators are William K. McKeown, Leopold Choquette, and G. E. Chart, all of Montreal.

Midland Woodproducts, Ltd., has been incorporated at Toronto, with a capital of $200,000, to operate sawmills and manufacture all kinds of wood products at Midland, Ont. The provisional directors are James Playfair, David S. Pratt and Dwight J. Turner, all of Midland, Ont.

Dominion Foundries & Steel, Ltd., has been incorporated at Ottawa, with a capital of $6,000,000, to acquire and take over as a going concern the Dominion Steel Foundry Co., and the Hamilton Steel Wheel Co., both of Hamilton, Ont. Incorporators are, Edward H. Ambrose, Henry A. Burbidge, and John R. Marshall, all of Hamilton, Ont.

TRADE GOSSIP

The Imperial Steel & Wire Co. of Collingwood, Ont., will be reincorporated with a Dominion Charter under a new name of the Imperial Steel Corporation.

Tungsten Prices Advance.—The price of tungsten has advanced and promises to go higher owing to leading producers having advanced the ore to a new schedule operative since May 1, which fixes $20 a unit for 60 per cent. concentrates. This represents an advance of $3.00. The metal is now quoted at $2 to $2.15, New York.

St. John's, Nfld.—Inability to obtain steamers to transport their product to England has resulted in the decision of Lord Northcliffe and his assistants to shut down their large paper mills at Grand Falls. It is understood that most of the company's log choppers will take service in the forestry battalions being organized here for timber work in Great Britain.

Sarnia, Ont.—To facilitate the loading and unloading of steamers at the Point Edward freight sheds, six electrical trucks have been purchased and installed, each truck costing in the neighborhood of $3,600. The addition of this modern equipment to the other facilities in use at the sheds, completes one of the most modern freight handling depots on the Great Lakes.

Expect Steel Record.—Conservative steel manufacturers express the opinion that earnings of the steel companies in the current month will establish a new high record. The May earnings of the United States Steel Corporation are estimated around $45,000,000, which would be at the rate of $540,000,000 a year, a total of about $32,000,000 in excess of the par value of the entire common stock issue.

Steel Firm's Offer to Help Shipbuilding.—Advices from Washington state that Chairman Denman of the Shipping Board said that the steel interests had come forward with the offer to supply 400,000 tons of steel a month to aid in carrying out the Government's program. This information was received with much satisfaction by officials, in view of the situation which had been faced.

Record Price for Boiler Plate.—A report from Philadelphia, Pa., states that another high record of prices has been scored in the phenomenal eastern plate market. A sale of about 500 tons of marine boiler steel for delivery during the next five months has been made at 20 cents per pound, mill, or $400 per ton. Shipment is to be made to a gulf point. This is the highest price for any commercial quality the eastern plate market has developed.

Vancouver, B.C.—With a capital of $10,000,000 a new company for the manufacture of pulp and paper is to be started in British Columbia under the title of the Whalen Pulp & Paper Mills, Ltd., according to the statement made by James Whalen, who is president of the concern. Three companies have been absorbed—the B. C. Sulphite and Fibre Co. of Mill Creek, the Empire Pulp & Paper Mills of Swanson Bay, and the Colonial Lumber & Paper Mills of Quatsino, Vancouver Island.

Payment for G.T.P. Rails.—In the House of Commons at Ottawa recently, Hon. Frank Cochrane told Mr. Oliver that payments to be made to the Grand Trunk Pacific for rails taken for use in France, would be fixed under the War Measures Act, subject to adjudication by the Exchequer Court. Mr. Cochrane said that new rails would have been cheaper than those obtained by dismantling portions of constructed roads. The military authorities, however, were unable to wait until new rails could be procured, and moreover the rail mills were not in a position to accept contracts.

Munitions Embargo Placed by Railways.—Munitions plants in Toronto are affected by the embargo ordered from the Montreal offices of the C.P.R. and G.T.R. against the acceptance of munition shipments until the congestion at ocean ports is eased and freer accommodation is provided for the transfer of shipments to ocean bottoms. This is the first time since the outbreak of the war that an embargo has been placed on munitions. Local railway officials declare that the shortage of ocean bottoms is alone responsible for the condition which has made the embargo necessary. The embargo does not affect 18-pound shrapnel, 4.5 in. howitzer shells and 4.5 in. shell forgings.

Features of Steel Demand. — Of the many varied products of the steel mills those attracting most interest at the moment are shipbuilding and railway equipment supplies. A tremendous impetus has been given to the entire trade by the heavy demand from both of these consuming industries, which has gone far in adding to quantity of unfilled tonnage at the mills. The United States Shipping Board is rapidly laying its plans for the construction of three millions of vessel tonnage within the next year and a half. This added to some two million tons now actually under construction in the various shipyards of the country swell the aggregate to the total of 5,000,000 tons.

REFRIGERATION

Montreal, Que.—The Frick Ice & Refrigeration Co. have sold a three-ton refrigerating machine to D. D. Drulard, of Windsor, Ont., and another unit to the Montreal Arena, Montreal.

Montreal, Que.—The York Manufacturing Co., York, Pa., has sold a 120-ton refrigerating machine and high side to the International Manufacturing Co., Montreal. The plant was installed by the Carrier Engineering Corp., New York.

TENDERS

Three Rivers, Que.—The City Council are receiving bids on four turbine pumps, each having a capacity of between 2½ and 3 million gallons per day.

Paris, Ont.—The Town Council are calling tenders for a centrifugal pump with a capacity of 750 gallons per minute. Full particulars may be obtained from G. H. Armtsrong, sec.-treasurer.

St. Lambert, Que.—Tenders will be received up to May 28, for the supply and installation of a horizontal shaft centrifugal pump, electric motor and switchboard. Specifications may be obtained from H. A. Gibeau, town engineer.

Sudbury, Ont.—Tenders will be received up to May 28, for the supply of all materials and erection of a 500,000-gallon steel stand pipe for the Town of Sudbury. Plans, specifications. and forms of tender may be obtained at the office of the Superintendent, R. H. Martindale.

Stratford, Ont.—Tenders will be received up to Monday, June 11, for furnishing and constructing a radial brick or concrete chimney and foundations for the refuse incinerating plant on St. Patrick Street, Stratford. Specifications and forms of tender may be obtained from the office of A. B. Manson, city engineer.

Toronto, Ont.—Tenders, addressed to the Secretary-Treasurer of the Board of Education, will be received May 31, for lumber, white lead, turpentine, linseed oil, etc., required for repairs. Specifications may be seen, and all information obtained at the office of the Superintendent of Buildings, Administration Building, 155 College Street.

Toronto, Ont.—Tenders addressed to the Secretary-Treasurer of the Board, will be received until May 30, for science apparatus and chemicals, garden hose, lawn sprinklers, garden shears, etc. Specifications may be seen, and all information obtained at the office of the Superintendent of Supplies, Administration Building, 135 College street.

Toronto, Ont.—Tenders will be received up to June 5, for the sale and removal of four horizontal return tubular boilers from the west boiler room of the City Hall, Toronto. Copy of terms and conditions may be seen, and tender form obtained, together will all information relative thereto, at the offices of the Property Department, City Hall.

Toronto, Ont.—Tenders, addressed to the chairman, Board of Control, will be received up to May 22 for two five-ton gasoline motor trucks and two three-and-a-half ton gasoline motor trucks for the Department of Street Cleaning. Forms of tender and conditions of tendering may be had on application at the office of the Street Commissioner. City Hall.

Brampton, Ont.—Tenders will be received up to June 5, for the several trades required in the erection of a school building for the Brampton High School Board. Plans and specifications may be seen at the office of the architects and at the office of R. H. Pringle, Secretary of the Board, Dominion Bank Chambers, Brampton, Ont. Wickson & Gregg, Architects, Toronto.

Chatham, Ont.—Tenders for all trades except structural steel work, will be received until June for proposed 8-room additions and alterations to Queen Mary School. Plans and specifications may be seen at Architect's office, No. 1 Victoria Block, Chatham, or at the office of C. E. Beeston, Secretary of the Board of Education, County Building, Chatham. John Methuen, architect.

Brantford, Ont.—Tenders will be received by the secretary of the Board of Water Commisioners, until May 28, for two electrically-driven turbine pumps with capacity of 300 gallons per minute each, also electric motors and equipment. Specifications, etc., may be seen at the office of the secretary of the Board, Brantford, or at the engineer's office, Chipman & Power, Mail Building, Toronto.

Winnipeg, Man.—Tenders, addressed to the chairman, Board of Control, will be received up to May 18 for the supply and delivery, f.o.b. cars Winnipeg, freight and duty paid, to siding on Saskatchewan Avenue at the Decarie incinerator, of two horizontal water tube boilers. Plans, specifications and form of tender may be obtained at the office of the city engineer, 223 James Avenue, Lambert, Chambly Co., P.Q.

St. Johns, Que.—Tenders addressed to J. A. Raymond, secretary-treasurer of St. Johns, P.Q., will be received at his office, until May 30, for the construction and supplying of material in connection with the following works:—1—One water tower; 2—Pumping and mechanical gravity filtration plant. Plans and specifications can be seen at the office of Messrs. Ouimet & LeSage, 76 St. Gabriel Street, Montreal, engineers of the City of St. Johns, P.Q.

CATALOGUES

Power Machinery.—MacGovern & Co., New York, have issued a list of used power plant and electrical machinery and contractors equipment, etc.

Vises and Anvils.—The Columbian Hardware Co. are distributing to the trade a catalogue dealing with the line of "Columbian" vises and anvils. The various types are illustrated and principal dimensions given for each size.

Cross Cut Saws.—Simonds Canada Saw Co., of Montreal, have issued an attractively illustrated catalogue of their Crescent groud cross-cut saws, saw tools and files. The pamphlet also embraces illustrations of Dominion Saw Works Co.'s cross cut saws. Complete specifications and price lists are shown. A wide range of hand ice saws is also shown. Copies will be supplied on request.

PREPARING A LARGE SIEGE GUN FOR ANOTHER ROUND ON THE WESTERN FRONT.

Procuring Special Machines for Munitions Manufacture*

By H. V. Haight**

The subject matter of the accompanying paper relates to the machining and assembling of British 18-pdr. shrapnel, and 8-inch Howitzer shell, each of which is discussed separately. In addition to what may be termed his local experience, the writer has visited numerous shell shops both in Canada and the United States; he is, therefore, in a position to express a worthwhile opinion as to machines required, and indicate whether they should be bought or made.

As no two manufacturers of munitions follow the same methods or use the same machines, any opinions the writer may advance must be based on his own experience or observation and will be subject to confirmation or modification when compared with the experience of others. The writer's firm is engaged in machining and assembling the British 18-pdr. shrapnel and the British 8-inch howitzer shell. Under the plan of organization of the Canadian Imperial Munitions Board, the work is all sublet by the latter. The contractor for machining and assembling shrapnel, for example, is furnished with forgings for the bodies, also with finished component parts such as discs, sockets, copper bands, tubes, tin cups, bullets, etc., and with the other materials required, such as resin, solder, paint and shipping boxes

18-Pdr. Shrapnel

When undertaking the first contract for shrapnel, our firm had a machine shop which could be converted to its production, also an experienced working force. As output increased, and as the regular work picked up, additional machines were purchased or made, until all the regular tools had been withdrawn from shrapnel service. In many cases these regular machines were withdrawn because required for making our regular product; however, there was the additional reason that for four-fifths of the operations the new tools purchased or made were more productive than the regular tools used at first. Our experience, therefore, has covered the use of standard machine tools, special purchased machines, and special machines made by ourselves.

Fig 1 shows the shell at several stages, and the numbers indicate the operations described below.

Cut off open end.—Standard 4-inch cutting-off machines with air expanding mandrils. Production 900 in 8 hours. We also tried a special machine to cut off both ends at one setting and another machine of the type of a pipe-threading machine, but both proved failures and were returned to the makers. On the regular machines the air mandril is preferred to the universal chuck as it is much quicker and costs less to keep in repair.

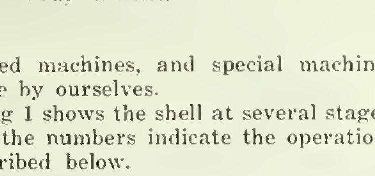

FIG. 1. INDEX OF OPERATIONS IN MACHINING SHRAPNEL.

Rough-turn body.—We used at first heavy 24-in. engine lathes, 24-in. Gisholts, Loswing lathes, etc., with fair results but we are now using single-purpose lathes of our own make which produce more work and are much simpler to keep in repair. These lathes have cast-iron spindles, $6\frac{1}{2}$ in. in diameter in the front bearing, with driving gear integral with the spindle. They have tight and loose pulleys on the back-gear shaft, thus eliminating countershafts with their troubles. The fed is by belt, eliminating feed-gear troubles. The work is chucked on an air expending mandril and turned with a bar cam to give the necessary enlargement at the open end of the shell for the subsequent bottling.

Rough-face base.—We have used 36-in. engine lathes, 42-in. and 60-in. vertical boring mills, 36-in. planers, 30-in. planer-type millers, etc., on this work, but have abandoned them all for 4-in. standard cutting-off machines On milling machines the tool upkeep is too great, on planers the work is hard to hold, on planers and boring mills the intermittent cut is hard on the machines, and on all except the cutting-off machines the labor cost and upkeep are too high. On the cutting-off machines the regular universal chuck is omitted and a plain hinged chuck used, as a universal chuck will not stand shell work. The regular cutting-off tool blocks are replaced with a tool block to hold a facing tool. When the countershaft clutch pulleys give out, they are replaced with tight and loose pulleys. Each man runs two of these machines.

Finish-face and turn base.—Standard 16-in. lathes, with air collet chucks supported by steady rests, give satisfactory service on this operation. Only hand feeds are used

Rough and finish bore.—It has been found best to rough bore on one machine

*Paper presented at the Spring Meeting, Cincinnati, Ohio, May, 1917, of the American Society of Mechanical Engineers.

**Plant Chief Engineer, Sherbrooke, Que.

and finish on another. Turrets are not desirable on shell work, where they can be easily avoided. We used a well-known make of turret lathes on this work, but they proved pretty light and required considerable repair. They were eventually withdrawn for regular work and replaced by special boring lathes of our own make, in which the work is held inside the spindle by an air collet chuck. Two different feed mechanisms are in successful use, one on a central rack with power feed and air return, the other a crank and "Scotch Yoke" with hand feed. Another Canadian munitions plant made very successful boring machines from gasoline-engine patterns. We built a double-spindle lathe for this work but it proved a failure.

Rough band groove.—This work is being done on cutting-off machines and also on lathes of our own make. In both cases the work is held in push-out air collet chucks. No longitudinal feed is required and only a hand cross-feed.

Finish band groove.—This consists of undercutting the edges and forming the waved ribs. Potter & Johnston automatics are in successful use and stand up well. It has been found, however, that a man can do more work on one machine than he can on two or three, so the automatic feature is of no use on this work. Regular 20-in engine lathes with the special fixtures, and simple lathes of our own make with similar special fixtures, are now preferred as they produce rather more work. This is the only operation on which universal chucks are still used, but they will probably be superseded by air chucks. Two different purchased waving machines, built for this purpose alone, were tried but proved unsuccessful.

Harden.—We used at first muffle furnaces, with cast-iron pot muffles holding eight shells, but now we use large semi-muffle furnaces holding 50 shells. The furnaces are built to design furnished us by another shell manufacturer, but appear to be copied from a commercial furnace. We used pyrometers at first, but now the operators go by the color. An "Irite" pyrometer is used to train new men.

Bottle.—The noses of the shells used to be heated by dipping in a pot of lead. This was rather expensive in the use of lead, and also gave a little trouble from lead poisoning. The present method is to heat in an oil furnace having holes through which the shells project into the furnace. A water-jacketed front was tried, but fire-brick with iron thimbles has been found better. We built these furnaces after the style used in another shell shop. The bottling presses used at first were air presses which we made ourselves from drill sharpeners, but the present practice is to use geared crank presses which are purchased. After bottling, the shell is put back in a similar furnace to anneal the nose.

Shot blast.—The regular foundry sand blast was used at first, but present practice is to use a small shot-blast machine of our own make This has two jets, one of which cleans the band groove and the other the base. The shot-blast gives practically no dust, and can be used anywhere in the shop.

Turn and thread nose.—This requires a fairly heavy turret lathe, and we are using both 24-in. engine lathes and also single-purpose lathes of our own make, both of which are equipped with turrets. We prefer the latter lathe as they take the work inside the spindle and eliminate the steady rest. Air collet chucks are used. This is the only operation on the shrapnel where a turret is used and this requires five holes of the turret.

Grind nose and grind body.—Standard grinders, slightly modified for the wide wheels used on shell work, give satisfactory results, as do also special purchased shell grinders. The grinding machine manufacturers, of all the regular machine-tool builders, come out with the greatest credit from the viewpoint of shell production. In most other cases the shell manufacturers themselves have built more suitable machines than either standard or special machines built by the machine-tool manufacturers.

Grind base.—Simple machines of our own make give good results.

Press copper band.—Two different hydraulic band presses, both designed and built by other shell manufacturers, are giving good results on this work.

Turn band.—A heavy engine lathe with special equipment and an air collet chuck gives good results, but costs more money than a very good special band-turning lathe, built by another shell manufacturer

Fill.—This is nearly all home-made equipment and hardly requires detailed description here.

Turn socket.—A 16-in. engine lathe is heavy enough for this. A clutch on the back gear is convenient. A turret is not desirable.

Paint.—We use with satisfaction a small portable machine of our own make, driven by a 1/6-h.p. motor.

Single-Purpose Lathe Features

The foregoing does not cover the use of purchased single-purpose lathes, of which there are now a large number of designs on the market, but from experience with three or four types of these on 8-in. shells, it appears that they should give good results on shrapnel work. The features they should have would be a large spindle, 4in. to 5 in. diameter, with the hole at least 1 5/16-in., strong drive and feed, a good feed-engaging clutch, or better still a drop worm. The counter shaft should have tight and loose pulleys, though the use of air chucks will largely eliminate countershaft troubles, as it is not necessary to stop to change work. It is better, however, to have tight and loose pulleys on the headstock and eliminate the countershafts, as they take up so much room overhead that it is difficult to group the machines to best advantage. The elimination of countershafts also reduces the cost of belting, which is quite an item.

A special point for consideration is the depth of dovetail on the carriage, for the cross-slide. This should be 1⅛ in. to 1¼ in. deep, but there are at least two of these lathes on the market with dovetail ⅜ in. to ½ in. deep, and a taper gib. The very small surface is not sufficient to resist the side strain of a cam, which is used on two of the operations, and the height is not sufficient to use a straight gib with set screws. It is usually necessary to replace the regular cross-slide with a special cross-slide, and when doing so it is much simpler to use a straight gib with set screws, rather than a taper gib.

Shrapnel Summary

To sum up, a manufacturer starting to make shrapnel would be well advised to consider the following suggestions:

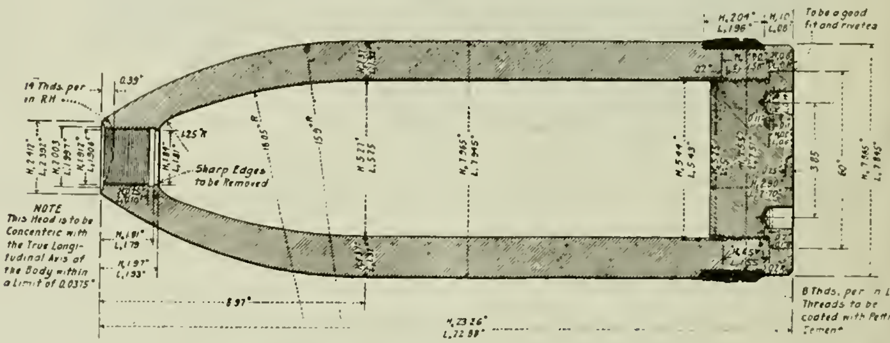

FIG. 2. BRITISH 8-INCH HOWITZER SHELL.

Perform simple operations and use simple machines. Do not try to perform several operations at one setting, and do not buy automatics, turret lathes or other complicated machines.

A pretty safe and satisfactory plan is to get a quick start at some fraction of full intended capacity, and to add equipment and build up production after some experience has been gained.

Suitable purchased machines for making a quick start would be regular cutting-off machines, regular engine lathes 16-in. to 24-in. swing, simple single-purpose lathes, regular or special grinders and such special machines as bottling presses, band presses and band lathes.

It will be worth while to consider the organization of a lathe-building department to supply many of the machines required to increase the capacity. This department might also undertake the making of air chucks, waving devices and other special attachments, and thus relieve the tool room. Later, this department would become a repair department, which is an important and busy department when work is being pushed day and night.

8-inch Howitzer Shell

The British 8-in. howitzer shell (Fig.

2) is forged with the base open. After finishing the shell, the base is closed with a screwed base plug called an adapter. When we undertook a contract for these shells, we decided to make most of the lathes and other equipment ourselves, and for that purpose organized a lathe-building department. These lathes gave very satisfactory results as to first cost, upkeep, and rate of production. They take up much less floor space than the standard or special-purpose lathes which we were offered, and enable the machines to be grouped so that the work can be handled very cheaply. The longest beds of these lathes are 8 ft. 6 in., and many of them are 7 ft. and 6 ft. 6 in. long. The absence of countershafts is also a feature which enables the lathes to be closely grouped. The lineshafts run crosswise of the shop, while the work also progresses across the shop from operation to operation. Long tables for holding the work run lengthwise of the shop between the ends of the lathes. The operator takes a shell from one table and, after completing the operation on it, places it on the next table, thus avoiding trucking.

Experience on this shell has confirmed the principle of doing simple operations on simple machines. For example, at first we undertook to rough-bore, ream and counterbore at one setting, but soon found it was better to make three separate operations on three different machines. The only operations which are done at the one setting are those which it is essential to have concentric. Thread milling had been superseded by tapping. We know of other manufacturers who have tried to make this same shell by doing a large number of operations at one setting, and have made special machines for that purpose. They have, however, since discarded this plan and have come around to the general principle of doing one operation at a setting.

While the special-purpose lathes which we have built for this work have proven very satisfactory and have a number of advantages over purchased machinery, yet it took some time to get them designed and built. As in the case of shrapnel, the manufacturer would be wise to purchase a portion of the machines necessary to get a quick start at some fraction of the desired ultimate capacity.

DIESEL ENGINES v. STEAM TURBINES

A COMPARISON of the cost of generating power by means of Diesel engines and steam turbines, together with a discussion of the different factors governing the profitable use of either type, is given in a paper read by Herbert Haas at the Arizona meeting of the American Institute of Mining Engineers. The author says that in places where neither cheap coal nor water power is available, and the price of oil fuel is increased by cost of carriage, the Diesel engine will become a prime mover of increasing importance. Where water is scarce the Diesel engine also shows to advantage, because about twelve times as much water will be required for condensing purposes with steam turbines under general conditions as is needed for jacket cooling of the two-stroke engine, while engines of the four-stroke pattern require only one-twentieth of the water. The following table of costs of generating power with four 2,000-kilowatt Sulzer-Diesel engines, direct-connected with alternators and exciters, is based on a fuel cost of $1.25 per barrel of 320 lb., and lubricating oil cost of 35 cents per gallon:—

TABLE I.—COST OF GENERATING POWER WITH FOUR 2,000-KILOWATT SULZER-DIESEL ENGINES DIRECT CONNECTED TO GENERATORS AND EXCITERS.

	Full load 12,000 h.p. 8,000 kw.	¾ load 9,000 h.p. 6,000 kw.	½ load 6,000 h.p. 4,000 kw.	¼ load 3,000 h.p. 2,000 kw.
Kw. hr. per year	70,000,000	52,500,000	35,000,000	17,500,000
Barrels	140,000	105,000	70,000	35,000
	Cost per year	Cost per year	Cost per year	Cost per year
Fuel cost	£35,000	£26,200	£17,500	£ 8,750
Labor	3,780	3,780	3,780	3,780
Lubrication	6,130	4,599	3,066	1,533
Maintenance	1,440	1,440	1,440	1,440
Total direct	£46,350	£36,019	£25,786	£15,503
Interest and amortisation	17,280	17,280	17,280	17,280
Total cost	£63,630	£53,299	£43,066	£33,783
Cost per kw. year	7.9	6.6	5.4	4.2

The kilowatt-year is equivalent to 8,760 kilowatt hours. Three units work continuously, and one acts as a stand-by and the cooling water in circulation for 9,000 horse-power, working continuously, amounts to 8,000 to 11,000 cubic feet per hour with re-cooling arrangements.

In table II. the costs of operation under similar conditions, with power generated by two 6,000-kilowatt turbines, are shown. The turbines work with steam at 180 lb. pressure per square inch, steam temperature 620 deg. Fah., inlet temperature of condensing water 60 deg. discharge temperature 75 deg. Fah., quantity of cooling water per 6,000 kilowatt-unit, 74,000 cubic feet per hour. One generating set works continuously at full load and the other is a stand-by:—

TABLE II.—COST OF GENERATING POWER WITH TWO 6,000-KILOWATT STEAM TURBINES.

	Full load 8,000 kw.	¾ load 6,000 kw.	½ load 4,000 kw.	¼ load 2,000 kw.
Kw. hr. per year	70,000,000	52,500,000	35,000,000	17,500,000
Barrels	300,000	210,000	150,000	83,700
	Cost per year per kw. hr.	Cost per year per kw. hr.	Cost per year per kw. hr.	Cost per year per kw. hr.
Fuel cost	£75,000	£52,400	£37,400	£20,925
Labor, etc.	5,000	5,000	5,000	5,000
Maintenance	1,440	1,440	1,440	1,440
Total direct	£81,440	£58,840	£43,840	£27,365
Interest and amortisation	17,280	17,280	17,280	17,280
Total cost	£98,720	£76,120	£61,120	£44,645
Cost per kw. year	12.2	12.6	15.2	22.3

The selection of two 6,000-kilowatt rather than three 3,000-kilowatt steam turbines is made on account of the greater efficiency of the 6,000-kilowatt sets, while the selection of four 2,000-kilowatt Diesel engine units is justified by the author on the ground that larger engines are not any more efficient in fuel economy, and the relative much higher cost of this prime mover makes it a good policy to reduce reserve capacity to a safe minimum.

Prime Mover Selection Considerations

The author concludes that in general the selection of either type of prime mover will be governed by the following economic considerations:—

1—Fuel is of chief influence on the total power cost, where both the B.t.u. price and load factor are high. These conditions favor the use of the Diesel engine.

2—Interest and redemption (amortisation) are of chief influence on the total power cost with low B.t.u. price and low load factor. This applies particularly to stand-by plants, which are operated only occasionally or have to supply recurring peak loads. The installation cost of such plants must be kept as low as possible so as to avoid heavy capital charges distributable over a relatively small kilowatt-hours output of the station. Such conditions favor the steam turbine.

3—Exceptions to (2) are cases where the constant and instant readiness of the Diesel engine give it preference, and installation cost is of secondary importance. Here it is necessary to balance the cost of keeping boilers under steam continuously against the difference of interest charges of steam turbine and Diesel engine plants.

4—For power plants erected at the source of the fuel, either in the oilfields, or at the coal mine, prime movers will be selected, costing least to instal, i.e., steam turbines, since fuel expenditures will weigh less than interest and redemption charges.

5—In many cases combination plants using Diesel engines for supplying the continuous and nearly constant main load, and steam turbines for furnishing periodically occurring peaks by the use of high-duty boilers with large water and steam spaces, capable of being forced when necessary, will prove most profitable.

6—Steam power will remain the cheapest power wherever waste-heat gases are available, as, for instance, gases from reverberatory smelting furnaces, where nearly one-half of the fuel used in smelting can be utilized for steam generation. Nearly 3,000,000 B.t.u. for every ton of charge smelted are thus available for steam generation, or about 150 horse power hour per ton of charge.

7—Up to capacities of 1,000 horsepower steam turbines can compete with Diesel engines only in special cases, such as supplying exhaust steam for heating purposes. For such small units, particularly for greatly varying loads, reciprocating steam engines are preferable. For larger plants, from 1,000 to 10,000 kilowatt capacity, careful analysis must be made of the relative advantages of Diesel engines and turbines, a knowledge of the load factor, fuel prices, and water conditions being necessary. For power plants larger than 10,000 than 10,000 kilowatts, using units from 6,000 kilowatts upward, steam turbines have the preference, unless a combination of high load factor, high fuel cost, and poor water conditions favor a Diesel plant.

VOLCANIC STEAM POWER

By D. Street.

THE harnessing of volcanic heat to industrial purposes is an idea that has often presented itself to the visionary mind, but it needed the war to bring the project into the realm of commercial actuality. The price of coal in the inland towns of Italy has now reached the fantastic level of $50 a ton, and, in consequence, attention has been turned towards other possible sources of power.

In Central Tuscany, as is well known, there are numerous cracks in the ground from which jets of steam spout high in the air with great force and constancy. As far back as 1903, tentative experiments were made with a view to using this steam for the generation of power. Holes were bored in the ground down to the source of the steam, which is a hard stratum of rock about 300 to 500 feet below the surface. These bore-holes which are lined with iron pipes and vary from 15 to 20 inches in diameter, were found to yield steam with a pressure of 2 to 3 and exceptionally up to 5 atmospheres, at temperatures varying from 150 to 190 deg. C. For several years these jets have not been diminished in their capacity nor does a new boring seem to interfere with the preceding ones, provided the distance from one to another is not less than 50 feet.

Method of Application

In a recent communication, Prof. Luiggi has given an account of steps that are being taken to use this steam on a large scale. Prince Ginori-Conti, to whom the earlier experiments were due, acting on the advice of the Tosi Works, of Legano—specialists in steam turbines and alternating electric generators—ordered three groups of condensing turbo-electric engines, each of 3,000 k.w., working with superheated steam at 1½ atmospheres, to be worked by the head of the volcanic steam jets. The steam is not used direct in the turbines, on account of the corrosive elements, which it contains, but fed to specially constructed multi-tubular boilers which, in turn, give off the steam used in the turbines. In the boiler the volcanic steam gives up about 60 deg. C. of its heat, the temperature falling from 180 to 120 deg. C. The steam generated in the boilers and used for the turbines is thus ordinary water steam, which, on its way to the turbine passes along aluminum pipes heated outside by a current of superheated natural steam, at 180 deg. C.

After passing through the turbine that steam is discharged into a surface condenser, the circulating water of which is in its turn cooled in an ordinary cooling tower. The condensed steam from the turbines is, of course, pumped back into the boilers and thus no natural steam ever come in contact with the turbines; by this arrangement corrosion is completely avoided. Professor Luiggi states that one of the 3.000 k.w. units has been at work since January, 1916, the second since April, and the third has just been started.

So far, the first two groups have worked quite successfully, and have been a great boon to the industhies of Tuscany, greatly crippled by the scarcity and high price of coal. The very successful harnessing of volcanic heat to an electric power house can be increased practically to hundreds of thousands of horse-power, as the region of the steam-jet extends for many square miles.

SULPHUR IN STEEL

By L. E.

THE long established belief that the effect of sulphur in steel is to make it unreliable has frequently been questioned in recent years. It has come to be generally recognized that high sulphur in pig iron is caused by poor furnace conditions, and that the sulphur is merely one indication of an iron that has not been properly produced. When this is the case, no amount of subsequent treatment under oxidising conditions in the open-hearth furnace can remedy the trouble, although the percentage of sulphur may be considerably reduced. The effects are carried forward into the finished steel, and there are good reasons for supposing that here also high sulphur is not so much the cause of unreliability as a symptom, and it might very well follow that a high sulphur is not harmful, provided the steel is not otherwise poor, due to insufficient reduction in the blast furnace. The question is receiving attention in many quarters.

In a recent American investigation tests have been carried out upon three steels having sulphur contents of 0.04, 0.09 and 0.16 per cent.. the other elements remaining for all practical purposes the same. All the specimens were heated just above the critical range, quenched in water, and various sets of specimens were reheated to different temperatures ranging from 300 to 600 deg. C., and again cooled in various ways. After heat treatment the specimens were tested for tesile strength and for resistance to repeated shock,—the Charpy pendulum machine being used for the latter test. This machine consists of a heavy pendulum, which drops from a fixed height and strikes the specimen which is supported from each end, and breaks it at notch. The pendulum then continues its swing and the height it reaches is registered. Knowing the weight of the pendulum, the height it falls, and the height it rises, a simple calculation gives the energy consumed in breaking the specimen.

The results of the tensile tests showed that sulphur does not lower the tensile strength. The figures obtained for elongation and reduction of area show that there was little difference in ductility between the low and medium sulphur steels, but the ductility of the high sulphur steels was slightly lower than the other two for most of the treatment. The average figures for the shock tests, except for the air and furnace cooled specimens, were highest for each treatment in the case of the low sulphur steels and lowest for each treatment of the high-sulphur steels. The widest difference appeared in steels which were quenched and reheated.

It is difficult to draw definite conclusions from the results, because of the newness of the shock tests and the difference of opinion among engineers regarding its value. The tensile tests were not favorable to steels with a moderate percentage of sulphur, while the shock tests showed a decided falling off in strength as the sulphur increases. Until the interpretation of the results from the Charpy machine is more fully understood, it is impossible to say to which set of tests the most importance should be attached. It is important that the question of sulphur in steel should be settled, not only because the elimination of sulphur entails much trouble and expense, but also because a moderate percentage of sulphur is an aid to machining. The low sulphur material drags, and the production of a smooth surface is very difficult. A slight increase in sulphur enables the machinist to produce a smooth surface without difficulty.

"An Irish hostess, when she asks if you'll have sugar in your 'tay,' holds out the bowl and absent-mindedly goes on with her conversation, allowing you to help yourself.

"An English hostess asks, "One lump or two?' and carefuly drops the sugar into your tea.

"If you should ask a Scotch hostess for a little more sugar in your tea, she would demand, with a note of surprise, 'And hae ye stirred it yet?'"

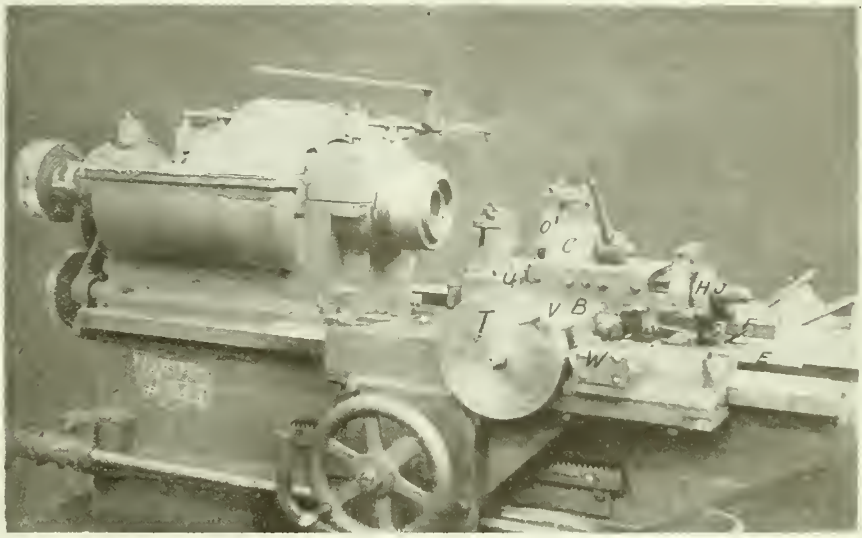
PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

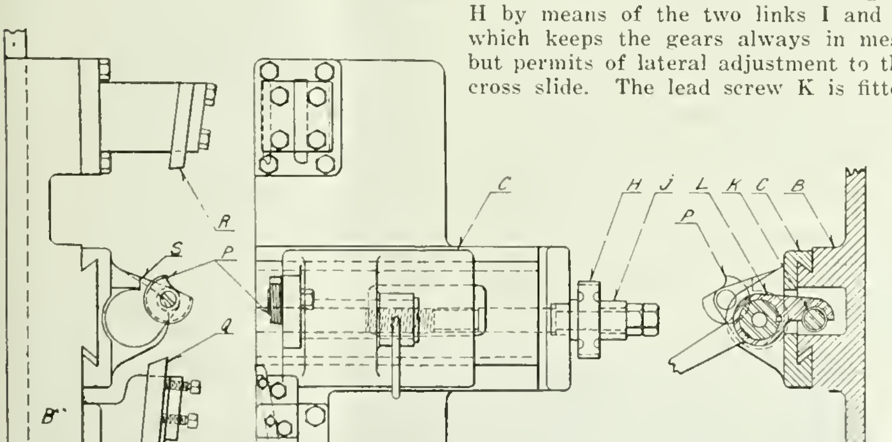
TURNING AND THREADING 8-IN. ADAPTERS

By R. Hamilton.

WHERE parts having two or more diameters require to be fitted together, as is the case on the adapters of the large shells, it is particularly desirable that the threading process should be performed at the same setting of the shell as that of turning the several diameters in order to avoid as far as possible any tendency to eccentricity that would prevent the accurate fitting of the parts. Where these operations are accomplished on different machines or at different settings of the shell, it is almost impossible to have the threaded portion concentric with the other two diameters—those of the pilot and the base portion. In addition to obtaining the highest degree of accuracy in machining of the parts, it is an important factor in connection with maximum production that the facilities for achieving this purpose be so designed that rapidity and economy are only secondary to accurate product. The illustrations herewith show the design of a fixture developed and used by the Ingersoll-Rand Co., of Sherbrooke, and placed on one of their special machines for the finishing of 8-inch adaptors. Fitted to the main saddle is the special cross slide B, which in turn carries the tool slide C, which operates at right angle to the cross slide and parallel to the axis of the lathe spindle. Secured to the lower part of the saddle and between the ways of the lathe is the forked bracket D, which supports the shaft E and also forms a pocket to retain the driving gear F and operating link I in a fixed position relative to the main saddle. The intermediate shaft G connects the lead screw gear H by means of the two links I and J, which keeps the gears always in mesh but permits of lateral adjustment to the cross slide. The lead screw K is fitted in suitable bearings so that the central line of the shaft is parallel to the slide C, and likewise the lathe spindle. The operating nut forms the lower portion of the bell crank lever L, which is keyed to the end of the short shaft M, this shaft being free to oscillate, but having no lateral movement. On the outer end of the shaft M is the flange O, which carries the bolt for securing the cutter P in the desired position. To prevent the pressure of the cut being transmitted to the feed nut, the collar O is provided with a shoulder that rests upon the stop S. The tool Q, held in the front tool holder, is used for turning the diameters of the adapters, while the tool R in the rear post, is for rounding off the corner of the pilot. The operation is as follows:—



TURNING AND THREADING 8" ADAPTERS



TURNING AND THREADING EQUIPMENT FOR 8" ADAPTERS.

When the adapter has been secured in the collet chuck and turned to size with the tools in the front and rear holders, the saddle is moved to the desired position for threading. The auxiliary lead screw K is revolved at the desired speed through the train of gears F, G, and H; the first-named, F, being feathered to the driving shaft E, which is driven by means of gearing at the head end of the lathe, this being set up in the ordinary way to cut the required pitch of thread. With the saddle in the correct position, the threading tool P is set in the usual manner by the movement of the cross slide, the operating handle T being graduated for close adjustment with an indicator finger U located at the top. The block V can be secured at any point around the circumference to determine the final position of the cut, as it comes in contact with the stop held in the block W fastened to the saddle of the lathe. At the completion of each cut, the handle L is pulled forward, thus releasing the nut from the screw, and the slide with the screw cutting tool is brought back to its initial position. This method of finishing the adapters has proven very satisfactory and highly efficient.

MATHEMATICS IN THE TOOL ROOM

By N. E.

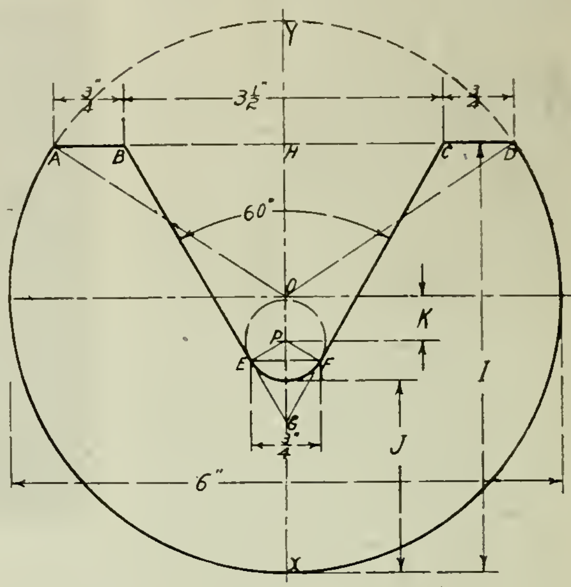
THE accomplishment of certain complicated machining operations in the jobbing shop or tool room, are generally performed by laying out the work with suitable tools, and working to the lines or dimensions thereby obtained. In order that accuracy may be maintained, it is often desirable, or even essential, that calculations be made involving the use of mathematics, so that the work can be checked after the work has been completed; or, as is often the case, before the work can be commenced. In the accompanying sketch is shown a shaper job that necessitated some figuring before actual machining operations could be started. A short length of shafting 6 inches in diameter, required a V-shoped groove of 60 degrees included angle, cut longitudinally, so that the opening B-C, across the top, would be 3½ inches; the total width of the chord A-D, on the cylindrical section, to be 5 inches, and the width of the bottom of the groove E-F to measure the same as the flats A-B and C-D, on the upper surface, at either side of the groove. As the width E-F was to be the chord of an arc, the extremeties E and F being tangent to the sides of the groove, it was desired to find the diameter of the hole required to give the correct chord, and the position of the centre P, or its distance on the centre line from the shaft centre O. It was also desired to know the distance I, measured on the centre line X-Y.

While this problem could be worked out in the ordinary method of laying it off on the end of the shaft, it does not give any means of checking the various dimensions after the work has been completed. To work out this problem by calculation involves the use of a certain knowledge of mathematics that should be more or less familiar to those mechanics who, from time to time, may be confronted with work of a similar character. As the width across the flat A-D is known, the shaping of this portion can be easily accomplished, but no check is given as to the proper dimension of the distance I. To obtain this, it is necessary to solve by the solution of triangles, for the dimension O-H. In the solution of right triangles it should be remembered that if the lengths of two sides are known, the third can be found by the axiom that the square of the hypotenuse, or longest side, equals the sum of the squares of the other two sides. Where the hypotenuse and one of the sides are known, the square root of the difference of their squares, will equal the length of the third side; therefore, from the sketch the formula will be:—

$\sqrt{(O\text{-}D)^2 - (H\text{-}D)^2} = O.\ H.$, or

$\sqrt{3^2 - 2.5^2} = \sqrt{9 - 6.25} = \sqrt{2.75} = 1.658$ inches; the distance I will be O-H plus the radius of the shaft, or 4.658 inches.

In every equilateral triangle the three sides are all of the same length, and the angles are similar, therefore, G-C and B-G are equal to B-C, or 3½ inches; and likewise, E-G and G-F are equal in length to E-F, or .75 inch. To find the position of the point G, we use the formula H-G $\sqrt{3.5^2 - 1.75^2} = \sqrt{9.1875} = 3.031$ in. To find the position of the centre P of the drilled hole, it is necessary to solve the right triangle GFP for the length G-P, by using the formula, hypotenuse side-adjacent divided by the cosine of the angle PGF, or .75 divided by .86603 equals .866 inch. As the three sides of an equilateral triangle are of the same length, it is obvious that the distance F-P, or the radius of the hole, will be one-half the length of the distance G-P, so the diameter of the drill to be used will be approximately 55/64 inch, or .866 inch. Then the dimension K, or the distance between the centre of the hole and that of the shaft (one the centre line), will be (O-X) — [(H-X) — (G-H) + (G-P)] = 3 — (4.658 — 3.031 + .866) = .507 inch. The dimension J will be O-K — (O-P P-F) = 3 — (.507 + .433) = 3 — .940 = 2.060 inches.



MATHEMATICS IN THE TOOL ROOM.

ROUGHING PROFILE ON 18 PDR. H. E. SHELLS

By B. S.

OWING to the parallel bore of the 18-pdr. high explosive shells, it is unnecessary to close in the nose in order to form the profile, and to give the shell the conical shape and reduce the diameter of the body so as to meet that of the base of the fuse, the surplus metal is removed by machining. Many methods have been adopted for this operation, due largely to the varied experience of the different manufacturers and the equipment they have to work with. With few exceptions the general practice is to cut this metal off by using box tools, these being arranged either in a stationary or moveable position; the former in the case where the shells are held in a chuck secured to the spindle of a lathe or drill press, and the latter where the shells are held firmly in a fixed chuck and the tools secured to the moveable member. The cut herewith illustrates a box tool bolted to the ordinary cross-slide tool rest, which is located in a central position with that of the lathe spindle. The shell A is held in the collet chuck B. The box tool holder is clamped to the cross slide as shown, and lined up if necessary to a central position, the two tools E, one on either side, being grolund to the desired shape of the profile and adjusted to correct position by means of the two set screws passing through the piece F, which is bolted and doweled to the body of the holder. The tool G, placed at right angles to the axis of the spindle, is set for facing the end of the shell and cutting the bevel for the seat of the fuse. The shaft H is secured to the centre of the holder and enters the bore of the shell, bearing on the inner base to gauge the final position of the profiling and facing tools. The tube I, shown at the top of the tool holder, is for the entrance of the cutting lubricant.

SPECIAL SHELL MACHINES

By J. H. R.

THE accompanying cuts illustrate a couple of machines designed and constructed by the Ingersol-Rand Co., of Sherbrooke, Que., for the production of 8-inch high explosive shells. In developing equipment for munitions purposes, this firm has, as far as possible, utilized one design of machine, modifying it where necessary to better suit the particular operation for which it is to be used, and yet, if desired, capable of being set up to perform another service, by the addition or subtraction of certain parts or attachments. By this method it has been possible to make many of the parts or details of a uniform character, and interchangeable if desired. The general practice has been to construct these machines with one speed for the lathe spindle, any variation from the designed speed being afterwards obtained by the size of pulley on the overhead shaft. Separate mechanism has been provided for operating the feeds; the parallel or axial movement being obtained by means of the gearing at the front of the machine, while the shaft that operates the cross feed is placed at the back of the lathe. Where it is possible to perform two operations at the same time, such as that shown in Fig. 1, where the open end is being cut off while the nose is being drilled, two saddles are provided so that the cross and longitudinal feeds can be operated at one time. The lathe illustrated in Fig. 1 is provided with a pneumatic cylinder for operating the expanding arbor that supports the shell. The forward saddle, or that nearest the head stock, has no lateral movement, except as is required for the setting in position, which when once set, is firmly locked to the ways of the lathe. On this particular machine, this cross slide is used for cutting off the open end to the required length for further machining. The moveable saddle at the rear is fitted with a fixed block on its upper surface, the hole that supports the drill being in line with the axis of the lathe spindle. As the nose of the shell has been previously centered in relation to the rough bore, it provides a good start for the drilling operation, which necessarily must be accomplished at a slower speed than would be employed if this operation was performed separately, but as the drilling of the nose is performed during the time that the base is being cut off, the time otherwise required for drilling is thereby saved.

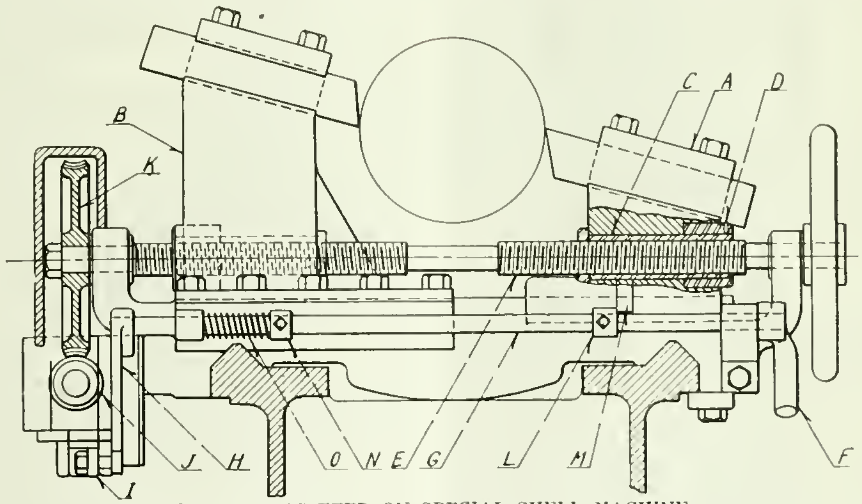

FIG. 3. CROSS FEED ON SPECIAL SHELL MACHINE.

Fig. 2 shows a view of the machine as designed for roughing the 8-inch adapters. As in the case of the unit above described, the two feeds are operated independently, this machine showing the arrangement of the mechanism for operating the cross feed. A feature in the design has been the extensive use of standard wood pulleys, these being generally adopted for the feed pulleys on the various machines. Where it was found possible, after experiment, that heavier feeds could be used to advantage, it was an easy matter to change the size of the pulleys to obtain the desired result. The line drawing, Fig. 3, shows the arrangement of the cross feed as applied to the cutting off machine, the principle being identical to that on the other machines where cross feed is required. In both the front tool holder A and the rear tool holder B, is secured a special nut C, which in turn is held in position by the lock nut D extending well into the body of each tool post. The

High Pressure Air Compressor Design and Application*

By Joseph M. Ford

Compressed air at high pressure is becoming an increasingly important medium in modern engineering practice and in naval warfare. The accompanying paper deals with the machines which produce high pressure air, leaving on one side the question of power transmission by compressed air. In passing, the principal advantages of this system are referred to, and will be seen to be of considerable value. They consist of the facility with which energy can be stored; the unlimited rate at which accumulated energy may be converted into useful work; and, apart from loss of efficiency, leakage cannot cause any awkward consequences.

ONE of the best instances of the adoption of high-pressure air as a medium for power storage is to be found in torpedo work. The torpedo is launched from the tube by means of compressed air, usually stored at a high pressure, and when in the water is propelled by an engine deriving most of its power from compressed air.

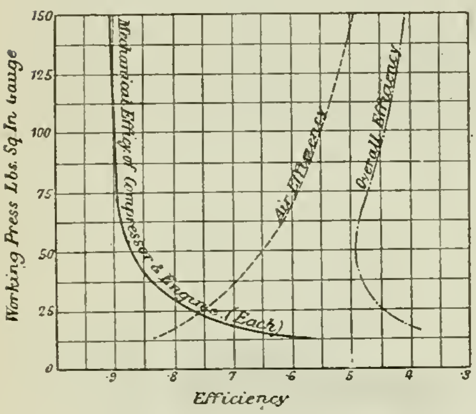

FIG. 1. SINGLE STAGE COMPRESSED AIR POWER TRANSMISSION. NO PREHEATING. MECHANICAL EFFICIENCY OF ENGINE ASSUMED TO BE SAME AS THAT OF COMPRESSOR. COMPRESSION IN LATTER AND EXPANSION IN ENGINE ASSUMED TO BE ADIABATIC.

The starting of prime movers of the internal combustion type of considerable size is almost invariably carried out by compressed air, except perhaps in very special cases, such as some generating sets, where the dynamo can be "motored."

In marine work, with engines of the Diesel and other types, reversing and manoeuvring involve the displacement of a considerable amount of the valve-driving mechanism—most conveniently accomplished by compressed air.

One of the principal applications, however, is in the Diesel engine works, where compressed air is used, not as a medium for energy storage in the usually accepted sense of the term, but to inject the liquid fuel into the working cylinders against the compression pressure of about 30 atmospheres (430 lbs. per sq. inch.)

In some oil-engined ships, high-pressure air is used for driving some auxiliaries, such as steering gear, main engine turning gear, small pumps, etc., and in submarines the air is used, among other things, for blowing the ballast tanks.

Pressure Adopted in Practice

Within limits, the lower the working pressure of the air, the higher the efficiency, but exigencies of space and weight may demand that the storage reservoirs shall occupy minimum space, in which case, for a given amount of energy stored, the pressure should be as high as possible—particularly, for instance, in a torpedo, where the dimensions and weight of power plant must be cut down to a minimum, almost irrespective of cost, and the pressures emplayed range accordingly from 2,000 to 4,000 lbs. per square inch.

With internal combustion engines, the design and type determine the pressure of the starting air. For example, gas, paraffin and petrol engines are frequently started with air at 100 to 300 lbs. per square inch. With Diesel engines of the four-cycle type about 300 lbs. per square inch usually suffices, whereas in engines of the two-stroke type the pressure may be as high as 1,000 lbs. per square inch. One of the disadvantages of using high pressures in this connection is that when starting a refractory engine—which does not readily pick up on fuel—the continued expansion of high pressure air in the working cylinders lowers the temperature to such an extent that the heat of compression is insufficient to ignite the injected oil. With reversing mechanism the obvious advantage accruing from the use of air at high pressures is that the dimensions of the servo-motors may be kept within small limits, which is of moment in some installations, although the higher the pressure the more difficult it is to maintain tightness and the better must be the fits, etc.

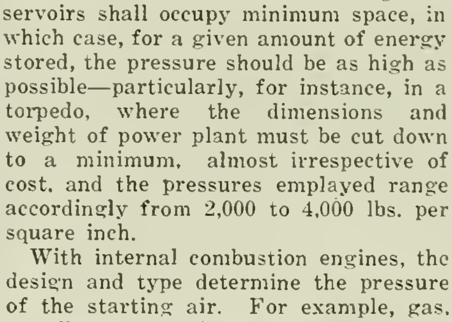

FIG. 2.

Initial temperature of air..	60 deg. F.
Initial pressure	14.7 lb. per sq. in. abs.
Final pressure	94.7 " " "

WORK REQUIRED TO COMPRESS AND DELIVER 1 CUB. FT. OF FREE AIR.

(i) Isothermal compression	3950 ft.-lb.
(ii) Polytropic compression ("N"=1.3)	4950 "
(iii) Adiabatic compression	5275 "

In this case 30 per cent. more work is required for adiabatic compression than for isothermal compression. Hence note importance of cooling during compression.

TEMPERATURES ATTAINED AT END OF COMPRESSION.

(i) Isothermal compression	60° F.
(ii) Polytropic compression ("N"=1.3)..	335° F.
(iii) Adiabatic compression	435° F.

Heat equivalent of work required for isothermal compression = area WYXZ.
Heat equivalent of extra work required if compression is adiabatic = area VWX (vertical shading).
Heat equivalent of extra work required if compression is polytropic = area TWX (diagonal shading).
Heat equivalent of work saved by cooling shaded horizontally.

For fuel injection, the air pressure is determined by the theoretical cycle of operations in the working cylinder, and varies from 600 to 900, and in extreme cases even to 1,000 lbs. per square inch, according to the particular design of engine, kind of fuel and load.

The question of driving auxiliaries by compressed air is a vexed one. Unless the air can be heated before expansion in the engine cylinder, low initial pressures should be used. With high pressures the re-expansion lowers the air temperature so much, due to work being done by the air, that snow forms and interferes with the working of the valves.

*Part I. of a paper read before the Greenock (Scotland) Association of Shipbuilders and Engineers.

throttle passages, etc. Fig. 1 shows the theoretical efficiency of a transmission system when there is no pre-heating. The mechanical efficiency of the engine at the different pressures is assumed to be the same as that of the compressor at the corresponding pressures. The "air efficiency" is the ratio of work obtained from the air in the engine to the work done on the air in the compressor. A considerable gain in efficiency may be effected if the air can be heated before use, especially when this can be inexpensively done—e.g., by the exhaust gases of an internal combustion engine. The advantages of this system are nullified, more or less according to particular circumstances, by the low efficiency. Practical considerations, such as the question of leaks, etc., favor low pressures, whereas such considerations as the size of pipes, cylinders and storage generally demand a compromise, although it is cheaper to make an efficient large low-pressure reservoir than a satisfactory small high-pressure one.

Simple Air Compression

By way of introduction a few points on the elementary thermodynamical aspect of air compression may assist towards the understanding of the special features of high-pressure compressors. If air be compressed isothermally, a certain amount of work has to be done—see Fig. 2, giving a theoretical indicator diagram for a machine delivering air at 80 lbs. per square inch. With isothermal compression the work required is represented by the area ABED. If the compression be adiabatic, then the additional work required is represented by the area BGE, from which it will be seen that the aim should be to secure isothermal compression, that is, to prevent increase of the temperature of the air during compression. Not only from the point of view of power absorbed should the temperature rise be small, but also for mechanical reasons, as later explained.

The index "n" in the standard equation $PV^n = C$ is in some ways a measure of the amount of heat abstracted during compression. With adiabatic compression its value for diatomic gases such as air is 1.41, and with isothermal compression its value is unity. In actual practice the amount of heat removed by a water-jacket on an air compressor cylinder is such that its value lies between about 1.28 and 1.35, the latter value being more applicable to large high-speed machines.

The line BF on Fig. 2 represents compression according to the law.

$$PV^{1.3} = \text{constant.}$$

This means that the saving in work effected by cooling the air during compression is represented by the area BGF Moreover, the reduction in the final delivery temperature is to be noted.

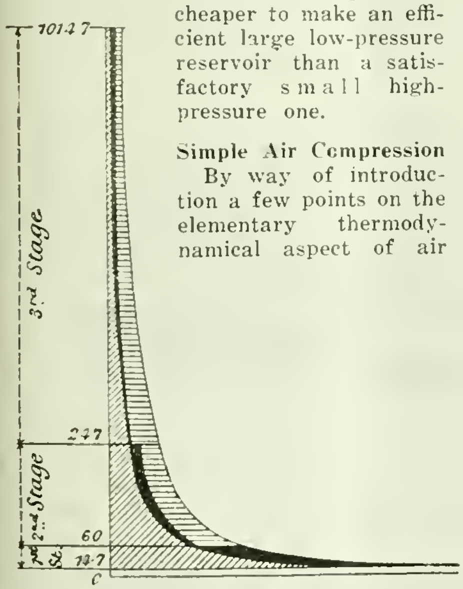

FIG. 4. Pv. DIAGRAM.

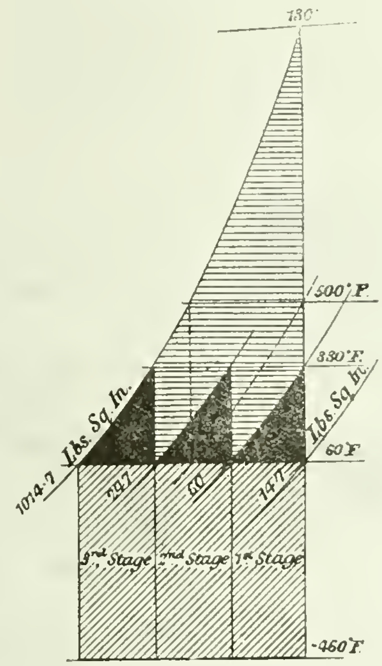

FIG. 5. Oo DIAGRAM.

THEORETICAL DIAGRAMS SHOWING SAVING EFFECTED BY STAGE COMPRESSION. COMPRESSION TO 1,000 LBS. PER SQUARE INCH GAUGE.

In an ideal compressor, i.e., one in which compression is isothermal, the work required per unit of air is represented by the diagonally shaded area of each diagram. If compression were carried out in one stage the work required is represented by the total area of the diagram. The horizontally shaded area represents the work saved by compressing in three stages and intercooling. The darkly shaded area represents the amount by which the work required for three-stage compression is still in excess of the ideal. Note the huge saving of three-stage over one-stage compression. In this case the saving is 29½ per cent.

The diagram in Fig. 3 is the "theta" "phi" diagram corresponding to Fig. 2. This shows rather more clearly the difference in the work required and temperature attained by compressing under the various conditions. The figure is self-explanatory.

Compression in Stages

When pressures of 1,000 lbs. per square inch and over are required, the temperatures attained by single-stage compression would be extremely high. If lubricating oil could be eliminated from the problem, careful design might succeed in producing a compressor that would stand the stresses set up by the high temperatures.

Lubricating oil burns in air at such temperatures, with the result that the pistons would become carbonized, the valves clogged and the pipes sooted-up. In addition, high temperatures have deleterious effects on tempered steel valves and springs. With large high-speed machines the temperature, coupled with the peculiar fatigue phenomenon, makes it well nigh impossible to get satisfactory working with temperatures higher than those consequent upon about six compressions in one stage.

If the excessive work of compression and high temperatures are to be avoided, the heat must be abstracted from the air in the period between the start of compression and the commencement of delivery. Jacketing alone is insufficient. The method that suggests itself is to compress the air a small amount, then withdraw it from the cylinder, cool it to atmospheric temperature, and return it to the cylinder. Next, move the piston further to compress the air still more, and repeat the cooling process, and so on, until the required pressure is attained. This is virtually the method adopted in practice, except that in lieu of carrying out the whole process in a single cylinder, one cylinder is devoted to each stage of compression, and between each stage the air is passed through an intercooler to reduce its temperature to the initial atmospheric temperature. The saving in work effected by stage compression with intercooling is shown in Figs. 4 and 5. The PV diagram, Fig. 4, has been drawn for a three-stage machine compressing to 1,000 lbs. per square in.

If the heat of compression could be removed as fast as it is generated, as with isothermal compression, the work required to compress unit volume would be represented by the diagonally-shaded area. This is the ideal condition. If the compression were carried out in one stage and no heat were removed—that is, if the compression were adiabatic — then the work required to compress unit volume of air would be represented by the total area of the diagram, that is, the diagonally, plus the black, plus the horizontally shaded part. The ratio of this total work to that required in isothermal compression will be noted. If, again, the air were compressed adiabatically to 60 lbs. per square inch only and then cooled to its initial temperature, its condition will then be the same as it would have been had it been compressed isothermally. From this point the second stage of compression is carried out and the cooling process repeated, meaning that the area of the second stage diagram is only the diagonally shaded portion plus the black portion, the horizontally shaded part being completely saved, due to the reduction in the volume of air dealt with, as a result of the intercooling.

Similar conditions obtain in the third stage, the horizontally shaded part again representing work saved. The work required for adiabatic compression in three stages is thus represented by the diagonally shaded portion plus the black portion, which latter represents the amount by which the work required is still in excess of the ideal.

Fig. 5 is the "theta" "phi" diagram corresponding to the PV diagram in Fig. 4.

The corresponding areas are similarly shaded. In addition to the work required, this diagram shows the temperatures attained in compression under the various conditions. The reduction of the temperature due to staging is clearly shown. The 1,300 deg. F. is a theoretical value, 500 deg. F. is the temperature which would be attained were the compression carried out in two stages, and 330 deg. F. is the result of three-stage compression. In the case under consideration the total work is equally divided between the stages, whereas in actual practice this condition does not generally hold exactly.

The temperatures attained in the cylinder when air is compressed to various pressures in one, two or three stages, with intercooling, are given in Fig. 6. Piston friction and the effect of the cylinder walls have been neglected. As previously stated, the high temperatures could not be dealt with in practice. The temperatures given for two and three-stage compression are based on the assumption of perfect intercooling, which condition holds for well-designed machines. In some plants where there is a copious supply of cold water, and where intercoolers of liberal dimensions are fitted, the air can be cooled between the stages to less indeed than the initial temperature.

Fig. 7 gives the air horse-power required to compress 1 cub. ft. of free air per minute in one, two and three stages to various pressures, and shows how the power required approaches the ideal (isothermal compression), and the ill-effects of inefficient jacketing diminish as the number of stages is increased. For example, with air compressed to 1,000 lb per square inch in one stage, according to the law $PV^{1.3}$ = constant, the power required would be 0.46 a.h.p. per cubic foot; but if the cooling were very inefficient, so that the compression were adiabatic, the power would rise to 0.53 a.h.p. per cubic foot—an increase of 15 per cent. With three-stage compression, according to the same law, the power required would be 0.32 a.h.p. per cubic foot, and in this latter case, assuming that the cooling were inefficient, the power would only rise at the most to 0.335 a.h.p. per cubic foot—an increase of 5 per cent., against the 15 per cent. obtained when compression is carried out in a single stage.

Apart from the questions of efficiency and temperatures, an advantage of staging is the reduction of crankpin loads and stresses generally—the reasoning being exactly the same in this connection as for a compound or triple-expansion steam engine. Theoretically an infinite number of stages is required, but practical considerations, such as the multiplicity of parts, the low mechanical efficiency, weight, cost, etc., limits the number of stages.

Pressures and Number of Stages

The best practice is as follows: The maximum terminal pressures are, for one stage, 80 to 100 lb. per square inch; two stages, 600 lb. per square inch; three stages, 1,500 lb. per square inch; four stages, 2,500 to 3,000 lb. per square inch; five stages, 4,500 lb. per square inch; and above 4,500 lb. per square inch; six or seven stages to 6,000 lb. per square inch, which is about the highest pressure for which an air compressor has been constructed.

In the case of very small machines these pressures, for a given number of stages are often exceeded in order to reduce complication. For example, machines have been constructed and work quite satisfactorily when compressing to 2,500 lb. per square inch in two stages. The temperatures attained, however, make it necessary to carry out the cylinder lubrication by soapy water.

Effects of Cylinder Clearance Volumes

An important consideration in the design of a multi-stage compressor is the computation of the clearance volumes of the various cylinders. By clearance volume is understood not merely the volume of the space which separates the piston from the end of the cylinder when the crank is on dead centre, but, in addition to this, the volume of all valve ports and pockets, space behind piston rings if these are air-packed, and, in short, any space into which the air can be compressed, without passing through the delivery valve. With an ordinary single-stage compressor, such as would be used to drive pneumatic tools in a shipyard, the designer aims to reduce the cylinder clearance to the minimum, for by so doing a greater quantity of air is delivered per stroke than would be the case with a larger clearance. Fig. 8, which is a theoretical card for a cylinder compressing to 80 lb. per square inch, is given in explanation. With zero cylinder clearance the volume of air delivered is represented by CD, whereas with 10 per cent. clearance and the same cylinder dimensions the volume delivered becomes FD. Less air is drawn into the cylinder per stroke, since the air left in the clearance space re-expands along DE, for a portion of the suction stroke, as shown, and the suction valves do not open to admit a fresh supply of air until the point E in the stroke is reached. In this way the volume of air aspired is only EB, as compared with AB—the volume dealt with in the same cylinder without clearance. The ratio $\frac{EB}{AB}$ is known as the Indicated Volumetric Efficiency, and in this particular case is about 69 per cent. The smaller the clearance space, the nearer will E be to A, i.e., $\frac{EB}{AB}$ will be greater, and a larger volume of air will consequently be dealt with per stroke.

With a large clearance a larger cylinder is required to deliver a given amount of air than with a small clearance, yet the indicated work done per unit volume of air dealt with remains the same, although the larger cylinder makes for a heavier and more costly machine, with greater piston loads, so that in general practice the clearances are made as small as possible. Referring again to Fig. 8, the higher the compression is carried, the further will E be removed from A, that is, the higher the delivery pressure at which a given cylinder is working, the less will be the indicated volumetric efficiency. Further, if the clearance air receives heat from the cylinder and piston whilst expanding, the law of expansion will approach the isothermal and the pressure of the clearance air will take the longer to drop to the suction pressure.

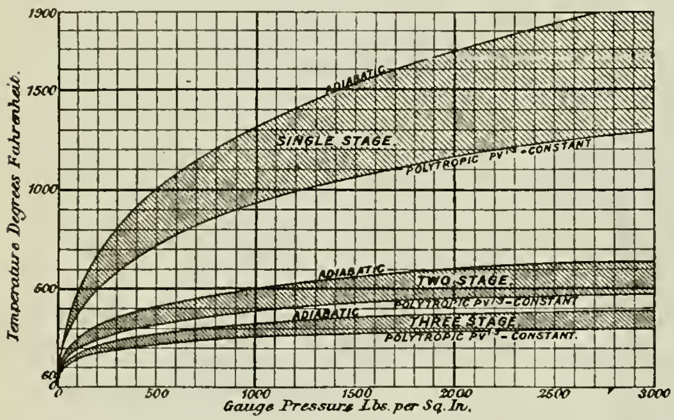

FIG. 6. TEMPERATURES ATTAINED WITH ONE, TWO AND THREE-STAGE COMPRESSION TO VARIOUS PRESSURES. INITIAL TEMPERATURE IN EACH STAGE OF COMPRESSION ASSUMED TO BE 60° FAH.

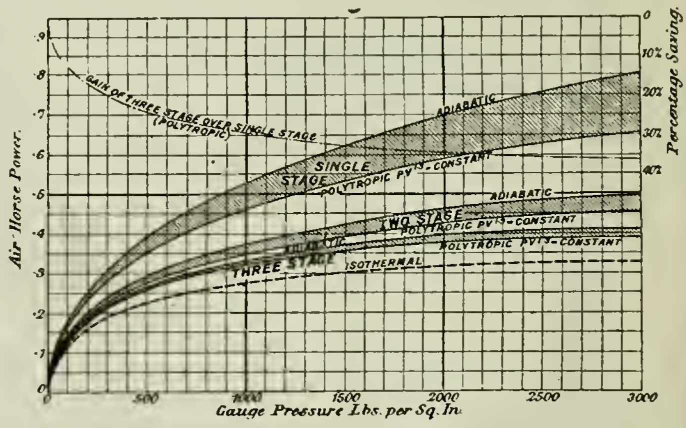

FIG. 7. AIR HORSE-POWER REQUIRED PER CUBIC FOOT FREE AIR PER MINUTE WITH ONE, TWO AND THREE-STAGE COMPRESSION TO VARIOUS PRESSURES.

or E will be still further removed from A to G.

It is to be emphasized that the air should not receive heat whilst re-expanding, or, in other words, the clearance space should be as efficiently cooled as possible. The cooler the walls of the

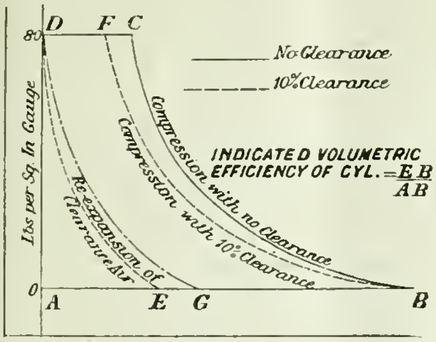

FIG. 8.

clearance space, the more rapidly will the pressure of the re-expanding air fall to the suction pressure and the greater will the ratio $\frac{EB}{AB}$ become. Moreover, if the clearance air receives heat whilst re-expanding, its temperature at point E will be considerably higher than the temperature of the incoming air. As a result of the mixing of the new supply with the hot clearance air, the temperature at the end of the suction stroke, i.e., at B, will be higher than it would have been had there been no hot air left in the cylinder at point E, thus reducing the weight of air dealt with per stroke and increasing the temperature of compression. In any case the temperature of the air at B must be higher than that of the suction air, owing to contact with the hot walls and piston.

In modern practice, the cylinder clearance volume for a single-stage compressor or low-pressure cylinder of a multistage machine is seldom less than 3 to 4 per cent. of the volume swept out by the piston. It is usually found that, within limits for practical reasons, the larger the machine, the smaller the percentage clearance.

If a single-stage machine were constructed to compress to a moderately high pressure, say, 165 lb. per square inch, the indicated volumetric efficiency at the best would not be more than about 80 per cent., whilst the ratio of volume of free air delivered to volume swept by piston would be very much lower still, due to the addition of heat before compression commenced. Further, the crosshead loads would be very great, due to the final delivery pressure being exerted on the whole area of the large piston. The twisting moment diagram for the machine would be uneven, and, perhaps of most consequence, the final delivery temperature would be excessively high.

If, on the other hand, the same size of cylinder were used with a high-pressure cylinder added thereto, so that the first only compressed to 37 lb. per square inch, the indicated volumetric efficiency would be increased to about 94 per cent., due to the lower delivery pressure bringing the point of the low-pressure diagram corresponding to E in Fig. 8 nearer to A. With the high-pressure cylinder mounted in tandem with the low-pressure, it is possible that the weight of the machine per unit of air delivered would not be more than when the compression was carried out in one cylinder. Staging nullifies to a large extent the effects of clearance volume on the volumetric efficiency of a compressor, besides obviating the difficulties with loads and temperatures.

In both the French and German languages the expression for clearance volume, literally translated, means "injurious space," yet the effects of clearance in some cases are beneficial. In a cylinder with no clearance the whole load at the commencement of the stroke due to the acceleration of the moving part comes upon the crank-pin. With clearance, the re-expansion of the clearance air helps largely to accelerate the masses, and an interesting case in this connection may be cited.

With steam-driven compressors it is common practice to mount the steam cylinders in tandem with the air cylinders, in which case the setting of the steam valves must be so arranged that admission is late instead of early, as is usual. If the full steam pressure were applied to the piston before the clearance air pressure in the air cylinder had become reduced by re-expansion, unnecessarily high loads due to these simultaneous full pressures, less the inertia effects, would be imposed upon the connecting rods, etc. High speeds with increased inertia forces tend generally to reduce crank-pin loads. With steam-driven compressors of the foregoing type the greater the clearance volume of the air cylinder the later must the steam admission be timed.

Effects of Clearance in the Higher Stages of a Multi-Stage Compressor

In a multi-stage compressor the work done in the various stages may be varied within fairly wide limits merely by adjusting the clearance volumes of the various cylinders, excepting the low pressure. Suppose, for example, it is required to reduce the proportion of work done in the high-pressure stage of a three-stage compressor in which the high-pressure clearance volume is 10 per cent., and with stage pressures—low pressure 45 lb. per square inch, intermediate pressure 300 lb. per square inch—working against a final delivery pressure of 900 lb. per square inch.

The work done in compression varies as the ratio of final to initial pressure, so that any desired reduction in any given stage can only be effected by reducing this ratio, or in this case by increasing the high-pressure suction pressure, since the final delivery pressure is fixed. The compressor capacity being unaltered, an increase in the high-pressure suction pressure necessarily involves a corresponding reduction in actual volume of high-pressure suction. Since the volume swept by the high-pressure piston remains the same, it is clear that the only way to ensure a reduced suction volume is to decrease the volumetric efficiency of the high-pressure cylinder by increasing the clearance volume, with the result as shown in Fig. 9, where the high-pressure diagram with the original 10 per cent. clearance, together with the diagram resulting from an addition of 20 per cent. extra clearance, are given. The area of the diagram is considerably reduced, the high-pressure suction pressure (the intermediate-pressure delivery pressure) rises from 300 lb. per square inch to 375 lb. per square inch (gauge-pressure), this increase being necessary in order to get the whole of the air into the high-pressure cylinder. The effect on the low-pressure delivery pressure is slightly to increase it, due to the reduced volumetric efficiency of the intermediate pressure cylinder, resultant upon the expansion of the intermediate pressure clearance air from a higher pressure. The actual increase in low-pressure delivery pressure depends upon the intermediate pressure clearance volume. If the intermediate pressure, cylinder had no clearance volume, which is impracticable, the low-pressure pressure would remain unaltered. The slight increase in low-pressure delivery pressure somewhat reduces the volumetric efficiency of the compressor.

The simple method of altering the distribution of work would be convenient where the high-pressure delivery temperature was found to be excessive (see later), or in cases where the turning moment was unsatisfactory. The clearance volume can be increased by the addition of a hollow pocket, but cannot so easily be reduced.

Some multi-stage compressors are required to work for long periods at varying delivery pressures, or, in the case of a charging compressor, at a constantly increasing pressure from atmospheric to the full bottle pressure. With Diesel engines it is usual to regulate the blast pressure by throttling the fuel-injection

FIG. 9. DIAGRAM SHOWING RESULT OF INCREASING CLEARANCE VOLUME IN HIGH PRESSURE CYLINDER.

air compressor suction, so that instead of compressing and blowing the excess to waste, only the requisite amount is dealt with. The effect on the distribution of work, temperatures, etc., occasioned by this throttling should be considered—especially with marine engines, where the compressor may run for long periods in this condition.

In all machines there are certain stage pressures which give the best all-round running, as regards temperatures, loads, balance, etc., for each delivery pressure. If these stage pressures are accurately determined for the normal final delivery pressure, then it is safe generally to assume that the particular stage division of work so obtained will also be the best proportion for any other delivery pressure at which the machine is likely to work. With Diesel engine fuel-injection compressors this state of affairs rarely obtains. In a three-stage compressor designed for 800 lb. per square inch working pressure, and run at, say, 900 lb. per square inch, the low-pressure and intermediate-pressure pressures will not increase in proportion to the final delivery pressure—actually in the majority of cases they alter little. By suitably proportioning the cylinder clearance volumes of the various stages the machine can be made automatically to divide the total work between the stages in a given proportion, no matter what the delivery pressure may be.

Figs. 10 and 11 show approximately the stage pressures which would be obtained in three machines of the same capacity when working at different pressures. Each machine is designed for a delivery pressure of 900 lb. per square inch, and at this pressure the stage pressures are: low-pressure, 45 lb. per square inch (gauge pressure). The heavy lines on the diagram show what the pressures should be to secure an approximately constant proportional division of work between the stages. The lines marked (a) show the pressures which would obtain in a compressor having cylinder clearances of: low-pressure, 4 per cent.; intermediate-pressure, 5 per cent.; high-pressure, 10 per cent.

The rise in the stage pressures as the final delivery pressure increases is seen to be comparatively small. The lines marked (b) show the pressures with a compressor of the same capacity when the cylinder clearances are: low-pressure, 4 per cent.; intermediate-pressure, 10 per cent.; high-pressure, 20 per cent. Here it is seen that the rise in stage pressure is much more marked than in the first case, that is to say, with these increased clearance volumes the proportional division of work between the stages is more nearly constant than with the smaller clearances. The lines marked (c) give the pressures which would obtain with a machine having clearances: low-pressure, 4 per cent.; intermediate-pressure, 15 per cent.; high-pressure, 30 per cent.

In this case the rise in stage pressures as the delivery pressure increases approximates much more nearly to the "ideal;" that is, the proportional division of work between the stages is very nearly constant, so that the balance of the machine is more likely to be maintained than in the first case, and, further, the final delivery temperature will be lower, for in the first case, when the machine is working at a pressure higher than its designed pressure of 900 lb. per sq. inch, the high-pressure stage is taking more than its designed share of the work. For example, if the first machine (case "a") were run at 1,200 lb. per square inch, the compression ratio in the high-pressure cylinder would be:—

$$\frac{1215}{335} = 3.63$$

If the last machine (case "c") were run at 1,200 lb. per square inch, the high-pressure compression ratio would be:—

$$\frac{1215}{370} = 3.28$$

This means that the temperature attained in the machine with the large clearance would be less than in the machine with the small clearance on account of the smaller compression ratio. Furthermore, if the large clearance is composed of a connecting pipe within a water-jacket, as is sometimes the case, the cooling during compression is improved, resulting in a decrease of the value of "n" in PV^n = constant, still further reducing the temperature. Again the clearance space being so efficiently cooled results in an increase in the value of "n" for the re-expansion of the clearance air. The incoming air mixes with this comparatively cool air, and consequently the initial temperature is not unduly raised.

The main point, however, is that by correctly arranging the clearance volumes the machine can be made to divide the total work into the best proportions for any delivery pressure with which the compressor may have to deal. A minor point is that with increasing delivery pressures piston leakage becomes greater, and the volumetric efficiency at the higher pressures is less than at the lower. If the low-pressure pressure increases with the delivery pressure, the indicated volumetric efficiency of that cylinder is decreased in addition—or, in short, the overall volumetric efficiency of the machine with the big clearances is slightly less than that of the machine with the small clearances when the delivery pressure is higher than that for which the compressor is designed.

The difference, however, is not worth considering. (It may be mentioned that the lines in Fig. 10 should not actually be quite straight. They are sufficiently accurate, however, as in practice it is impossible to estimate the pressures to within a few pounds.)

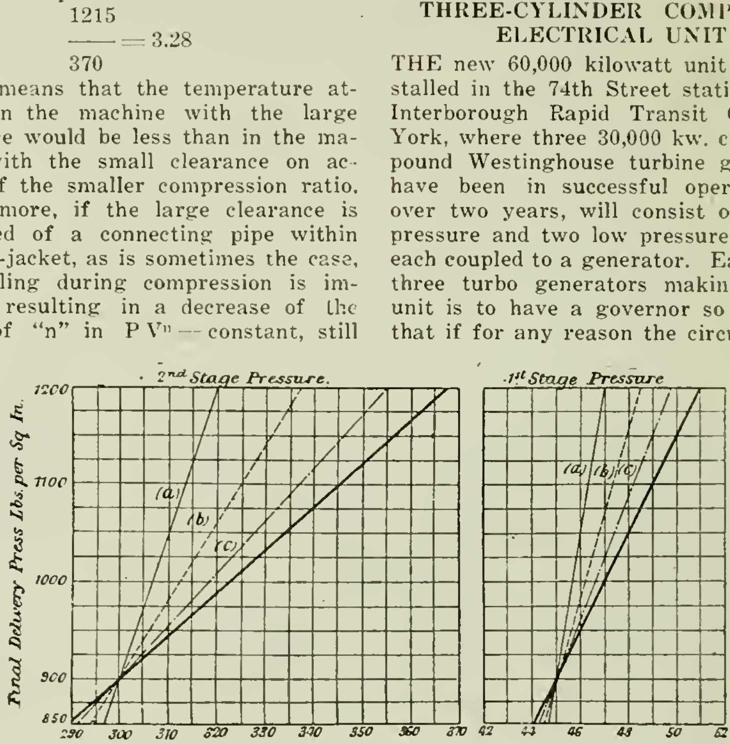

FIG. 10. FIG. 11.
DIAGRAM SHOWING APPROXIMATELY THE STAGE PRESSURES ATTAINED WHEN THE COMPRESSOR IS DELIVERING AGAINST DIFFERENT FINAL PRESSURES.

Each machine is designed for a final delivery pressure of 900 lbs. per square inch with L.P. and I.P. pressures of 45 lbs. per square inch and 300 lbs. per square inch respectively.
(a) For a compressor whose clearance volumes are: L.P., 4 per cent., I.P., 5 per cent., H.P., 10 per cent. of volume swept by piston.
(b) For a compressor whose clearance volumes are: L.P., 4 per cent., I.P., 10 per cent., H.P., 20 per cent. of volume swept by piston.
(c) For a compressor whose clearance volumes are: L.P., 4 per cent., I.P., 15 per cent., H.P., 30 per cent. of volumes swept by piston.
The heavy line shows what the pressures should be if the division of work between the stages is to remain in the same proportion for all delivery pressures.

THREE-CYLINDER COMPOUND ELECTRICAL UNIT

THE new 60,000 kilowatt unit to be installed in the 74th Street station of the Interborough Rapid Transit Co., New York, where three 30,000 kw. cross compound Westinghouse turbine generators have been in successful operation for over two years, will consist of a high pressure and two low pressure turbines, each coupled to a generator. Each of the three turbo generators making up the unit is to have a governor so arranged that if for any reason the circuit should open on the high pressure turbo generator, steam will be shut off from that particular one, and the two low pressure turbo generators will operate under governor control with high pressure steam. Likewise, should anything happen to both the high pressure and one of the low pressure turbo generators, or to the two low pressure turbo generators, the remaining one will operate and carry the load. The turbines which will operate at 220 lbs. absolute steam pressure, 120 degrees superheat, 20-inch vacuum, and the generators which will have a capacity of 60,000 kw. continuously, or 70,000 kw for two hours, are being furnished by the Westinghouse Electric & Mfg. Co., of East Pittsburgh, Pa.

WIRE ROPES FOR COAL MINES

By O. C.

THE importance of the mine rope is often underestimated but it is the essential life line of mine. The wire rope, by means of which coal is hauled to the earth's surface, constitutes a most vital link in the long chain of processes by which the coal is got from the mine and made to give heat, light, power explosives and countless other products essential to mankind. The designer of haulage or lifting tackle, especially for mining work, has a most exacting task, in which he must exercise the greatest prudence and foresight. The nature of the appliance is generally such that the failure of one rope almost certainly means disaster. In such a structure as a bridge one or even several members may fail, but the others will generally keep the whole together till the danger has been observed and precautionary measures taken, but the mine cage hangs by one rope, and if this fail, there is nothing to prevent the load from falling to the bottom of the shaft.

Complex Stresses

The nature of the stressing of a rope is very complex. In the straight portion between the winding drum and the load there is a direct pull on the rope as a whole, and it might be thought that the load that the rope would carry is equal to the sum of the loads which each individual wire composing it will bear. Experience has shown that this is far from so and that the strength of the rope falls short of the aggregate strength of the wire by as much as 10 to 35 per cent. Even if a sample of a rope, when tested in direct tensions, breaks at a load seven, eight, or even nine times that of the working load, it cannot at once be assumed that it is safe for continued use, for there are severe stresses brought into play due to the passage round the winding drum or pulleys.

This passage round the drum induces bending stresses very similar to those which occur in a beam subjected to a bending load. The nature of the plaiting of the rope reduces the intensity of these stresses far below what they would be in a bundle of straight wires bent round the same radius. Even so, a reasonable figure for the bending stress on a rope designed to carry a load of 10 tons per sq. in. due to the suspended load, would be 30 tons per sq. in. in crane design. Thus the total stress on the part round the pulley would be 40 tons per sq. in. By using more wires in the rope of smaller size the bending stress is reduced in proportion. Similarly it may be minimised by using larger pulleys and drums.

The effect of bending is rendered more serious by its constantly fluctuating nature. As the rope raises and lowers the cage, and is loaded and unloaded, the stress in it fluctuates between zero and maximum load and this leads to what is known as "fatigue." When a material is subjected to such a fluctuating load it will break under a much lower stress than it would if the load were steady. This effect may be seen by taking a thin strip of iron or steel and clamping one end in a vice. If the other end be bent over, the strip if soft will bend through a right angle, without cracking. But if it be bent to and fro, a number of times through a smaller angle, it will break right across. Experience shows however that there is a safe margin, and if the stress on the ropes does not fluctuate beyond this margin it will last practically indefinitely.

Soft Versus Hard Wire

It seems fairly certain that a soft wire withstands fatigue better than a hard one and consequently wherever possible makers use soft Bessemer steel of 40 to 45 tons per sq. in. tensile strength, or at least mild steel of 95 to 100 tons per sq. in. in preference to the harder but stronger plough steel of 110 to 120 or 135 tons per sq. in. For shallow mines, Bessemer steel ropes are much the most economical in first cost, but in deep shafts the weight of the rope itself which has to be supported becomes a serious factor, and for a given load this will, of course, be three times as much for a rope of 40 tons per sq. in. as for one of 120 tons per sq. in. Thus it is advantageous, if possible ,to employ hard wires for deep shafts. Fortunately it is possible to do this because the stress in the rope due to its own weight is so large, compared with the fluctuating load, as to damp out the effects of the latter. In addition, to the wearing strains already mentioned there is an effect due to the spiral lay of the wires and strands in the rope. The application of a pull makes these spirals unwind slightly, as does an ordinary spring. The slight movements of the wires against each other and against the pulley causes abrasion which has to be watched very closely in the periodical inspections of the ropes.

A rope experiences the greatest strain at, and before the moment of starting. Severe damage may be done if the load is thrown in to the cage too quickly, for if a load of say ten tons falls on a rope, suddenly, causing a shock, its effect is the same as that of a steady pull of twenty tons. During the first part of the wind, the load has to be speeded up from rest to a certain maximum speed of lift, so an extra force is needed to increase its speed, this being proportional to the rate at which the speed is increased. Thus, if the speed be raised to 50 ft. per sec., in twenty seconds, the force needed to accelerate, the mass is twice as much as if the same speed were attained after forty seconds. This accelerating force or inertia force must be felt by the rope, if the latter is attached rigidly to the cage and must cause a severe stress in the early part of the lift. As the above figures show, the rate of speeding up should be kept as low as possible consistent with rapidity of delivery from the shaft.

Reducing Stresses

The stresses due to shock and inertia are often reduced by using a special spring attachment between the rope and the cage. Rubber buffers have been introduced between the pulley bearings and their attachment to the bracket on the roof of the cage, so as to give some spring to the pulley when the load is lifted. Various arrangements are in use though the use of rubber means that it perishes rapidly under the exposure to the weather, so springs were resorted to. Whatever is the means used, the principle is the same, namely to interpose a spring between the rope and the load so that shock and inertia forces acting on the cage extend the spring instead of the rope, which if the spring is of the proper stiffness is almost entirely relieved of all but the steady load.

Ropes must be inspected minutely at frequent intervals. The most serious wear takes place at the lower end where a cap or clip is attached. At this point, shock effects and the tendency of a long spiral to twist and untwist are felt most severely. At each inspection the cap should be renewed and this gives the opportunity to cut off a short length which can be tested in direct tension as well as being prised open to reveal its internal condition. The individual wires are clamped at one end and subjected to repeated twisting and bending till they break. The rope should be discarded if the sample wires will not stand a certain number of repetitions of each kind of test, the criterion being fixed according to the physical properties of the steel from which the rope was made. A good plan is to reverse the wire each time it is recapped, as by this means each end in turn bears the shock and testing strains, and thus the damage is equalised. Great care should be taken to lubricate the ropes by allowing them to run in a trough having brushes fitted with lubricant on either side. A mixture of tar, summer oil, mica and axle grease is a good mixture. This reduces the abrasive effects of the pulley on the outer wires and of the wires on each other, and increases the life of the ropes by as much as 25 to 50 per cent.

Fixing Limit to Life of Rope

One port authority in Britain, the Belfast Harbour Board, follows the life of each of their ropes most carefully. For much of the work a standard 3 in. rope is used working over a 22 in. pulley. No rope works for more than four months continuously, being given periodical rests. It is discarded regardless of its condition after lifting 10,000 tons, and with the large 7 in. rope a life of ten years is allowed. These figures relate to crane work and not mine work but they show the extreme care which is bestowed on these appliances by responsible engineers. Some of the South African mines are over a mile deep and the results of a failure are too disastrous to contemplate. It was the fall of 40 Kaffirs through 4,000 ft, in Robinson's Deep mine which led to the abandonment of the flat rope, owing to the difficulty of inspecting it having allowed unsuspected faults to arise. The safest plan is undoubtedly to fix a length to its life and then discard it.

BY-PRODUCTS OF COAL DISTILLATION

By C. T.

THE abolition of smoke should be brought about simply and solely by distilling all coal before burning it. Everything at this moment combines to make this reform practicable, and it would effect a saving for the whole country of a hundred million pounds a year. First the increase of the price of raw fuel, quite apart from the war, has induced more care and thought as to its consumption. Next the advent of the internal combustion engine, by far the most simple, convenient, and economical prime mover so far discovered, has created an increasing demand with higher prices for benzol, gasoline and fuel oil. The passing of the horse and the gradual exhaustion of the nitrate beds of South America had led to higher prices for ammonia sulphate, which is one of the other valuable by-products of the distillation of coal.

No grate simple enough to be practicable will burn coal without smoke unless the coal be distilled first. Coke burns without smoke. Common gas coke, however, will not burn satisfactorily in many grates. Therefore speccial fuel must be made which will burn easily in an ordinary grate Raw coal can be distilled at a lower temperature than is used in ordinary gas-making, leaving about 10 per cent. of volatile matter in the coke. This fuel burns with a cheerful flame in any grate. Distillation at low temperature, seems likely to be the prevailing method; otherwise too much gas would be produced and too little of the valuable tars. Low temperature distillation produces the best yield of valuable tars and oil—notably, it produced a spirit with all the properties of gasoline. Normally England imports one hundred million gallons of gasoline per annum. Up British chimneys goes five hundred million gallons of gasoline per annum; and this is only one of the by-products of coal wasted in the riotous combustion of the open fire. The ammonia waste is still worse, for ammonia, if burnt, gives out no heat. It is a vital necessity in farming. Every ton of coal burnt might yield 50 cents worth of ammonia if distilled. From 200 to 250 million dollars worth of recoverable ammonia vanishes up British chimneys every year, with no return at all. A quarter of that could be easily retained by low temperature distillation.

POSITIVE AND FRICTION CLUTCHES

By T. J.

THE attempt to find a satisfactory form of clutch has yielded many excellent types and designs, but no clutch yet invented has shown such all-round superiority as to supersede all other designs. The claw coupling is the simplest and most effective of all clutches when once it is in action, for it consumes practically no power, and shows no wear, but it cannot be put in and out of a gear except at slow speeds, or when the machine is stopped. For a drive that can be connected or disconnected at full speed and under full load, some form of friction clutch is necessary. The cone clutch is the simplest of all friction clutches, and although innumerable other types of friction clutch have been introduced—segment clutches, band clutches, disc clutches, magnetic clutches, centrifugal clutches, etc.,—it still remains a prime favourite. The conditions to be fulfilled by the ideal clutch are many and diverse. It must be simple in construction, and free from undue wear; it must engage smoothly, and when engaged must grip firmly, yet there must be no "bite" that will prevent easy disengagement; the grip must not be incurred at the cost of heavy pressure on the moving part, as there will be a wear and loss of power; the amount of movement required to put the clutch into action must not be too great, and yet the clearance when out of action must be such as to ensure that there is no rubbing. These are but a few of the conditions to be observed.

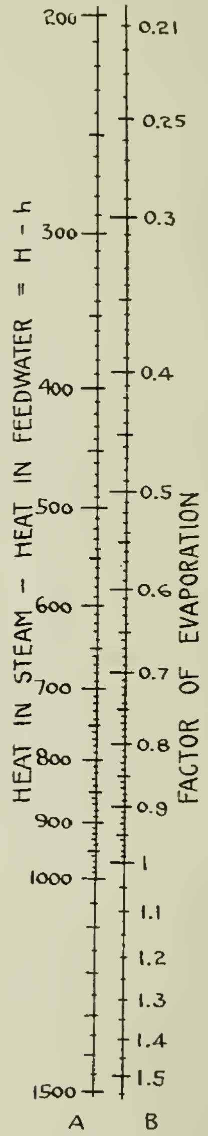
Theoretically the ideal clutch, as suggested by Mr. W. G. Gass, would be a combination of friction and positive clutch. It would employ a friction arrangement for starting up, and when that had done its part a positive drive would come into operation, and take all the work of driving off the friction surfaces. The designing of a combination clutch of this kind is not an easy matter. The difficulty would come in providing for its being thrown out of gear with the same ease as a friction clutch, for when the positive part of the clutch comes into action it is this part which will be doing the work, and will be under pressure, and to withdraw this part from engagement will present the same difficulty as is found with a claw coupling.

FACTOR OF EVAPORATION CHART

By N. G. Near.

THE term "Factor of Evaporation" is used a great deal in engineering — so much the writer thought it worth while to work up a chart on the subject in order that anybody can reduce ordinary heat values directly into factors of evaporation without doing any figuring.

For example, you look into your steam tables and find that the total heat in steam at a given pressure is 1,100 B.t.u. You also find that the feed water origin-



HANDY "FACTOR" OF EVAPORATION CHART.

ally contained 100 B.t.u. per pound. The difference H-h is therefore equal to 1,000 B.t.u.

Find the 1,000 in column A and directly opposite in column B is the factor of evaporation. You can see that it is very close to 1.03.

The figures above 1,000 in column A, are seldom used. They are used sometimes in connection with feed water heater computations, however, and in order to make the chart more complete, I therefore included them also. Thus, where the difference in heat values might be 300 B.t.u., the factor of evaporation is immediately given as 0.31.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

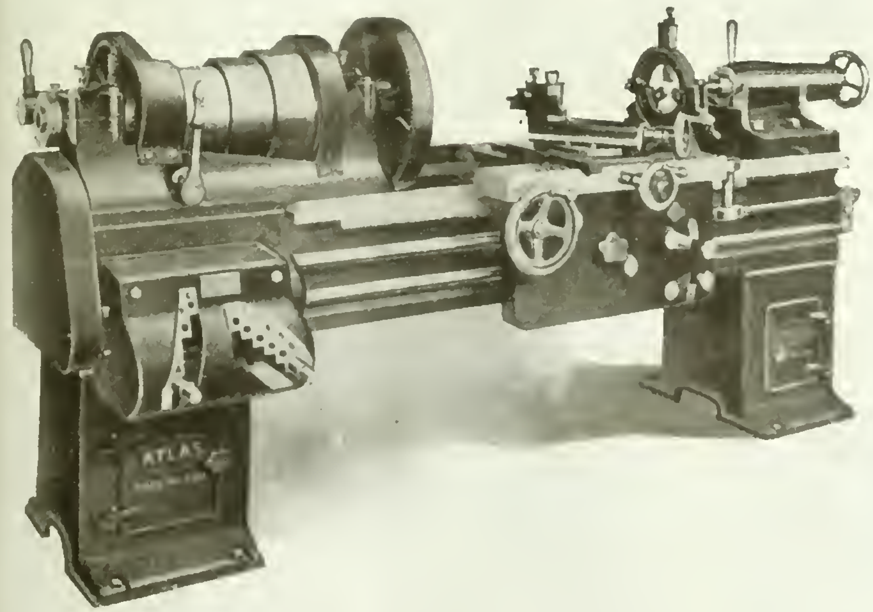
20-IN. DOUBLE BACK GEARED ENGINE LATHE

THE accompanying illustration shows the Atlas 20 in. engine lathe which is built by the Taylor Machine Co., Cleveland, O. It is equipped with double back gearing, quick change feed gear, and is built with 8, 10, and 12 ft. lengths of bed.

The head stock is offset from the centre of the bed to provide better distribution of the load on cross slide when engaged on heavy duty work. The spindle is made from a 50-point carbon steel forging, and runs in phosphor-bronze bearings with ring oilers. The three-step cone in conjunction with the double back gear gives nine spindle speeds. Front spindle bearing is 3½ x 6½ in. and the rear bearing 2¾ x 5¾ in. The total length of spindle is 36¾ in. and steel-bronze thrust bearing is fitted.

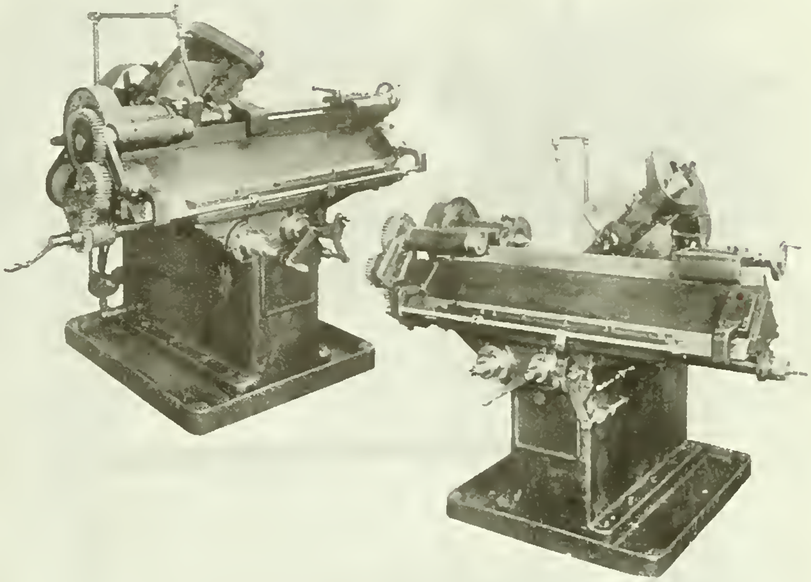
Heavy double-wall cross-girts are spaced two feet apart in the bed, giving ample stiffness. Two carriage-ways are provided on the bed, the front way being extra large. Owing to the use of a 20 per cent. steel mixture in the ways, the wear is confined to the carriage, thus avoiding loss of accuracy or alignment in the lathe bed.

The carriage vee is 2¼ in. wide, while the bridge is of unusual depth; the cross slide has a width of 9 in. The apron is a one-piece casting, with all bearings integral, and is pinned and bolted to the carriage. The lead screw is 1½ in. dia. x 4-pitch thread, and is made of 40-point carbon steel. The tailstock is of approved heavy duty type with double binding clamp on spindle, which is 3 in. dia., with 1 in. screw.



20-INCH DOUBLE BACK-GEARED ENGINE LATHE.

The feed gear box provides changes for 2 to 24 thds. per in., including metric threads up to 10 mm. pitch. The weight of this lathe with 10 ft. bed is 3,605 lbs.



HEAVY DUTY MILLING MACHINE. TRAVELLING TABLE TYPE.

HEAVY DUTY MILLING MACHINE

THE machine illustrated herewith has been developed by the Moline Tool Co., Moline, Ill., in order to facilitate the production of heavy spirals and worms used in their regular product. The machine is of the traveling table type, the cutter only moving in and out of cut.

The cutter drive is through a large gear mounted on the cutter arbor, a large proportion of the work done by machines of this type being such that it is possible to use a driving gear of much larger diameter than the cutter, thus conducing to both durability of the cutter and smoothness of cut. Where necessary, a smaller gear can be used. The cutter arbor is hardened and ground, and runs in bronze bushings, a tapered bronze bushing supporting the arbor outside of the cutter.

The lead screw is splined its entire length and is made much heavier than customary to avoid any torsional deflection. Change gears are 6 pitch and wide face. Indexing is accomplished by a plunger dropping into an index plate set into the back of the main spindle driving gear.

Work up to 8 in. dia. x 30 in. long, can be performed; the spindle is bored 3 9/16 in. Work can either be held in centres, or a collet or 3-jawed chuck can be screwed on the spindle nose. A steady rest block is furnished to which bushings can be fitted for supporting the work on its large diameter or on the shaft as desired. The regular equipment includes pump and piping with a tank in the base, a 2-speed countershaft, one index plate having any number of holes desired, one bushing for the steady rest block and change gears. Weight approximately 5,000 pounds.

SHELL NOSE TIGHTENING MACHINE

PERSPECTIVE view and detailed drawings illustrate a simple yet effective machine, largely in use, for tightening the noses of shells, as manufactured by George Pireous, of Leeds Bridge Works, Leeds, England. As shown in Fig. 1, it follows the lines of a simple on the ordinary lathe type of bed, so that it is applicable to any length of shell. The interesting feature is the method of securing the adapter for tightening the shell nose. This is shown in its assembled form in Fig. 4, the constituent units being illustrated in Figs. 5 to 8. The adapter is formed with a nose plug of cast steel (Fig. 6), with an external thread 14 per in. and 2 in. diameter, and an internal thread of 6 per in. Fig. 7 is a cast steel square head screw thread, cut to suit the internal thread of the plug, Fig. 5 is a mild steel clamp to grip the shell nose, and Fig. 8 a ¾-in. diametrical hexagon steel screw. The operation of tightening the shell nose is as follows:—

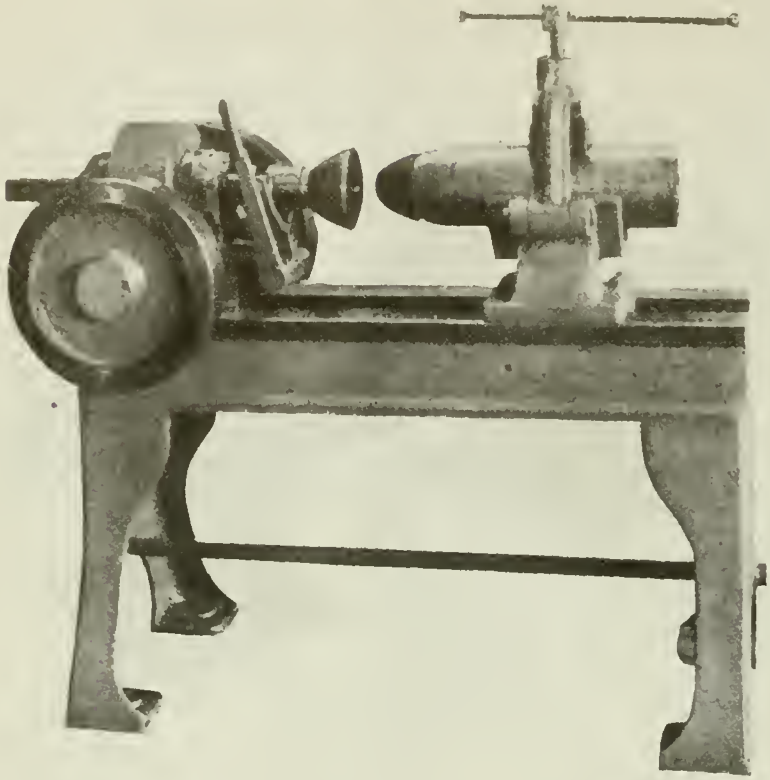


FIG. 1. SHELL NOSE TIGHTENING MACHINE.

lathe, the headstock spindle being driven (Figs. 2 and 3) by worm and worm wheel mounted on a cross-shaft, on one end of which is the flywheel and on the other the pulley, secured by a clutch with spring-pressed dog teeth to admit of slip should the speed exceed the predetermined rate. The countershaft belt pulley is arranged to drive in either direction.

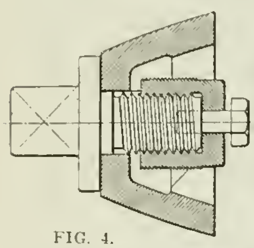

FIG. 4.

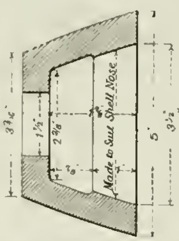

FIG. 5.

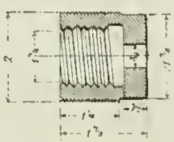

FIG. 6.

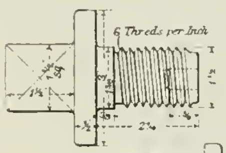

FIG. 7.

FIG. 8.

ASSEMBLY AND DETAIL OF ADAPTER FOR TIGHTENING SHELL NOSES.

The shell, it will be seen, is secured in a holder, arranged as desired, to accommodate any size of shell, which slides

The adapter is first screwed into the shell nose, which is then entered into the shell body, the square socket of the spindle being brought up to the square shank. The machine is next set in motion, and as the shell becomes tighter the nose plug revolves until the clamp grips the shell nose. When this is tightened home, the clutch on the machine automatically cuts the power off. In order to release the adapter the countershaft is reversed, the screw (Fig. 7) with coarse threads unscrews in the plug (Fig. 6), up to the shoulder of the set screw, which in turn unscrews. Thus in the distance between the shoulder of the set screw and the face of the plug the clamp is slack, and the whole arrangement can be unscrewed by hand.

WIRE NAIL MACHINES

A LINE of wire nail machines possessing novel mechanical and desirable operative features has been developed by Sleeper & Hartley, Inc., Worcester, Mass., as the result of several years activity in this line. Five sizes of these machines are built, handling wire from No. 17 to ⅝ in. dia. producing nails from ¾ in. to 10 in. in length.

The illustrations show three of these machines, the No. 2 machine, which occupies a floor space of 19 x 42 in. and weighs 750 lbs., having a capacity 400-2½ in. nails per minute, from No. 11½ wire.

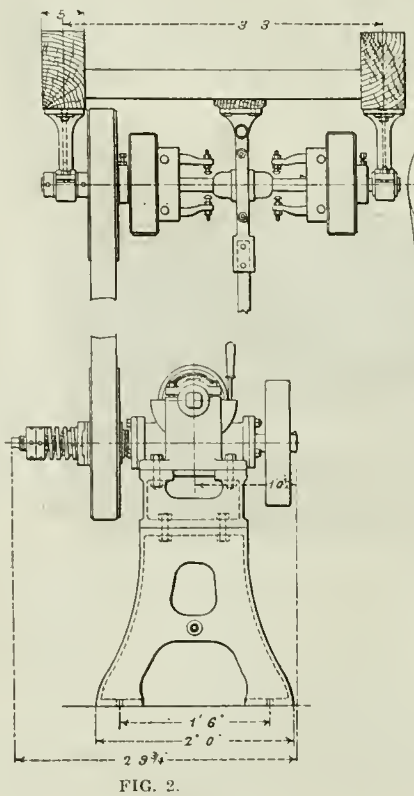

FIG. 2.

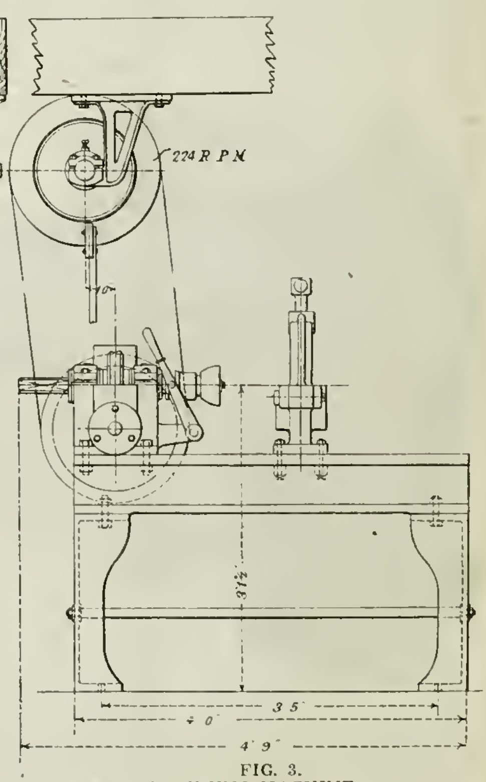

FIG. 3.

INSTALLATION DETAIL OF SHELL NOSE TIGHTENING MACHINE.

The objects aimed at in designing these machines have been high output, quiet operation, compactness, wide distribution of stresses, and accessibility. All of the working members are mounted on the top of this frame, being so arranged and mounted that they can be lifted off and the machine stripped down in a few minutes. No rotating cams are used, the working motions being accomplished instead by means of toggle joints, actuated from a single crank shaft. All these moving members operate in mechanical balance, smoothly and easily, and with a practically noiseless result. The power is expended in making nails—not noise—and the consequent wear and tear upon the machine is enormously reduced.

The pointing and heading operations have been separated, the heating effects upon the dies being thereby greatly reduced, and the working stresses much more widely distributed. This is effected by means of an intermittently operated carrier wheel (interposed between the pointing and the heading position, and provided with a series of holding jaws) which takes the pointed blank from the pointing dies, and carries it through an angle of 180 degrees into the heading position where it is gripped by the heading dies and headed. The finished nail is still held by the carrier wheel jaws until it reaches a point about 90 degrees further on, when it is automatically released and dropped.

In operation the wire is taken from the coil, and fed through the straightener rolls mounted on the feed slide. This feed slide is operated through an adjustable connection from a crank, and in the larger machines is provided with a quick return motion. A single revolution of the machine feeds a blank, cuts it off (at the same time pointing the incoming wire end) heads a previously cut-off blank on the opposite side of the carrier wheel, and moves the carrier wheel through a partial revolution, thereby releasing a previously headed nail.

A very notable feature of the design is the accessibility of the pointing and heading dies, any one of which may be lifted off in a few seconds for examination.

NO. 1 NAIL-MAKING MACHINE.

UNUSUAL INVENTOR AND HIS WORK

By D. A. H.

OUT in Los Angeles is an inventor whose story is the same as many another in most respects — little money to begin with, years of unceasing toil, etc.—but differs sharply in two other respects — his models, though crude, have every one been put to work and have paid for themselves and the patents covering them. The inventor is C. M. Mead and his improvements are widely known in the printing trade though until the recent formation of a corporation to manufacture the machines, they have not been on the market.

Beginning with a small rotary press, he improved it and developed it until it had a self-feeding arrangement and could print from a roll and could print several different "jobs" at one time. Further developments were, to obtain remarkably high speed, to produce the finest kind of multicolor work at high speeds, to fold and count and wrap. All of these things are being done and have been for years, but Mead's inventions combine many of them in one machine along with other little labor-saving devices, so that a great saving in production cost is possible, mainly through the handling now done from machine to machine.

To other inventors, Mr. Mead's faculty for making his models pay for themselves is most remarkable. Every inventor knows how much even one patent costs, of the expense of experimental work and materials, of the frailty of models, how ideas have to be rejected before they can be put into commercial form. Mead did printing on his first small press, he went out and solicited work for all his presses as they were perfected. Thus he had an income at all times, and what is more, he had the chance to try out his machines under practical conditions—to spend unlimited time in the study of the problems arising from every day hard work. His work was all done in sheds at the rear of his home and his models were built of odds and ends—scrap iron, wood, wire, bicycle parts, structural steel—things he could buy cheaply.

SPECIAL SHELL MACHINES

(Continued from page 559)

design of this nut makes it very easy to effect repairs, when the nut or screw become badly worn. When power feed is required, the handle F is moved upwards, the shaft G revolved through a portion of a revolution, and the crank on the back end draws the link H, and also the lever I, upwards, thus raising the worm J and bringing it into mesh with the worm gear K, which is keyed to the end of the cross feed screw E. The feed can be automatically disengaged at any desired point by the adjustment of the collar L on the shaft G. A stop M, fixed to the front tool slide comes in contact with this collar and forces the rod and levers over a sufficient distance to allow the worm to drop from a working position; when the tools are withdrawn by turning the hand wheel, the reaction of the spring O on the collar N brings the operating levers back to their initial position in readiness for the next cut.

EMERGENCY AND PERMANENT VALUES OF WOOD AND STEEL SHIPBUILDING INDUSTRIES

IT is of peculiar interest to note that the thousand wood vessel programme of the United States Government, involving the completion of that number of 3000-ton craft in eighteen months' time, has been passed up, in other words, investigation of the available resources has demonstrated the futility of the enterprise. Major-General Goethals, director of ship construction for the United States Government, speaking at the recent dinner of the American Iron and Steel Institute, pricked the wood-ship-in-quantity bubble by remarking that "when we consider that the birds are now meeting in the trees that were to go into these ships, and that the latter must have a speed of not less than 10½ knots if they were to escape being submarined, the proposition was hopeless."

Inasmuch, however, "as every little helps" so far as "bottoms" are concerned for the meantime overseas transportation of food and army supplies, the contribution of as many wood ships as material resources and plant capacity combined can put promptly into commission is in no sense to be discouraged, at the same time, it should be fully realized that, as a permanent national asset, wood schooner construction will at best have only a sentimental value. Even the steel sailing ship or barque has practically disappeared from ocean service, its displacement by the tramp steamer being quite as complete as was that of the wood schooner when steel became the material of construction. The best and most substantial contribution that Canada and the United States can make towards the rehabilitation of the world's ocean-carrying service is that of steel built, steam propelled ships, and in their plans and arrangements to that end they will be establishing and consolidating a coterie of industries within an industry of the highest possible value, making not only for permanence, but national progress in and development of a multiplicity of arts, crafts and specialized manufactures.

In advising the American Iron and Steel Institute of the results of his investigation concerning wood shipbuilding, Major-General Goethals took occasion to point out that, as ships were urgently required, and must of necessity be of steel, the co-operation of iron and steel manufacturers was a sine qua non of production. As a result of the plea made, the resources of the United States iron and steel industries are to be mobilized and placed at his disposal, and as an earnest of successfully carrying through such an undertaking, an administrative committee has been appointed, its personnel including such steel industry giants as Judge Elbert H. Gary, James A. Farrell, Charles M. Schwab, etc.

We in Canada don't seem to be at all awake to the immense importance attaching to steel shipbuilding, else long ere this tangible evidence would have been forthcoming of both steel plant and ship plant enterprise on our ocean highways and ocean shores. That hesitancy has been displayed in embarking on a wood shipbuilding programme doubtless admits of considerable justification because of its certain fleeting existence; why, however, an equal hesitancy should be shown towards broadening the scope of present, and the initiation of new lines of industrial endeavor whose outcome would be the creation and upbuilding of a Canadian built, equipped, manned and owned, ocean as well as lake fleet, of freight carriers of world competitive importance, there appears no good and sufficient reason.

The dual programme of wood and steel shipbuilding may have obscured the issue and complicated the situation somewhat, however, the wood construction feature as disposed of in the United States, may as likely as not allow more real concentration on that of steel, and lead even now to some worth-while developments in the latter. It is believed that the Algoma Steel Corporation, Sault Ste. Marie, Ont., have some comprehensive plans in process which will stimulate very materially our steel shipbuilding.

PROPOSED SECRET SESSION OF BRITISH ENGINEERS

APROPOS of the recent registration of Canadian engineers, at least those constituting the membership of our various Technical Societies and Associations, with a view to their services being made available to the Government either in consulting, administrative, or research capacities, a unique proposal has been made to secure a secret session of Old Country engineers, at which a representative of the British Admiralty would explain the means being taken to combat the submarine menace, and detail as fully and clearly as possible such problems connected therewith as yet remain unsolved. While it is realized that the Imperial Government can command, and has at its service, no end of what are believed to constitute the best scientific brains available, it is more than probable that much brain wealth is outside the fold. Our British contemporary, "The Engineer," very aptly remarks when discussing the subject that "useful inventions frequently spring from quite unexpected quarters, and that if the brains now officially at work have failed to solve the submarine problem, it is time others were tried, and high time that new fields of thought were explored."

The secret session proposed would be organized and managed by some such body as the Institution of Civil Engineers, the individual members to include men drawn from the country's principal engineering and shipbuilding establishments to the number of say three or four hundred, and of whose ability and integrity there could be no doubt. Secret sessions of the British House of Commons have been held on several occasions with a view ostensibly to stimulate moral support in the successful prosecution of the war, and such a procedure is of course quite valuable. A secret session of engineers such as now suggested would be double-barrelled in result; for not only would the strictly moral feature be stimulated, but some real genius would undoubtedly be disclosed and, in its train, a means or mechanism, or both, created and perfected which would effectually rid the seas of both the cold-blooded Hun and his submarine craft.

INDUSTRIAL NOTABILITIES

H. J. WADDIE, president and general manager, Canadian Drawn Steel Co., Ltd., Hamilton, Ont., was born in Edinburgh, Scotland, Oct. 19, 1869, son of John Waddie, shipbroker and Agnes (Sinclair) Waddie.

On the completion of his education, received at Royal High School, Edinburgh, and University College, Dundee, he was apprentice to Hawthornes, Ltd., engineers and shipbuilders, Leith, 1887-92; assistant manager, Dennystown Forge, Dumbarton, 1895; manager, Jarrow Forge & Engineering Co., Jarrow-on-Tyne, 1896; assistant managing director, Perfect Tube Co., Birmingham, 1897; general manager, Mannesmann Tube Co., Swansea, 1898-1901. In 1901 Mr. Waddie came to Canada as manager of the Algoma Tube Co., Sault Ste. Marie, which project failed to materialize. In 1904 he organized the present company.

H. J. WADDIE

Mr. Waddie's civic, social, and administrative activities have been very extended.—Chairman, Hamilton Centennial Industrial Exposition, 1913; chairman, Hamilton Branch, Canadian Manufacturers' Assoc., 1913-15; fellow of the Royal Colonial Institute; member, Toronto Exhibition Assoc.; director, Export Assoc. of Canada; chairman, Manufacturing Committee, Hamilton Recruiting League; chairman, Employment Bureau for Returned Soldiers; governor, Art Gallery of Hamilton; chairman, Committee British Sailors' Relief Fund.

He married Amy White, daughter of Col. J. C. White, Landore, South Wales, 1900; (deceased Apr. 30, 1916).

Clubs are:—Hamilton; Thistle; Burlington Country. Societies: A. F. & A. M. Recreations: Golf, Yachting, Angling, Travel. In politics Mr. Waddie is Conservative, and in religion, Presbyterian.

Mr. Waddie's residence is 50 Markland St., Hamilton, Ont.

The General Market Condition and Tendency

THE steady advance in prices of steel products continues and it is evident that the market is still far from the turning point. The insistent demand for steel and congested conditions at the mills indicate a continuance of the present upward movement which is further strengthened by increasingly heavy demand of the American Government. The position of the private consumer is steadily becoming more acute, owing to the urgent demand for steel for war purposes. Not only is material difficult to obtain, but prices are so high as to interfere with industrial enterprises. The price changes this week include 25c per 100 lbs., on iron and steel bars and small shapes. Iron bars are now 5c, steel bars 5.25c, and shapes 5.50c. Steel plates have advanced $1 and are now quoted at a nominal price of 9c. Black, blue annealed and galvanized sheets have also advanced, and still higher prices are looked for. Domestic foundry pig-iron is unchanged and the market is very firm. Producers are practically sold up for this year and have considerable tonnage booked for the first half of 1918. The scrap metal market is firmer and higher prices have to be noted on copper, brass, machinery cast iron and malleable scrap. Consumers are buying scrap more freely to replenish depleted stocks, thus strengthening the market. The non-ferrous metal markets are firmer, but prices are unchanged with the exception of lead, which has advanced. No marked improvement in the metal markets is expected until the American Government's requirements are known both as to quantity and prices. A good demand for machine shop supplies continues with indications of higher prices. The machine tool business is quiet and featureless.

Montreal, Que., May 28, 1917.—The industrial situation is in a measure unchanged from last week. The difficulty of securing reliable information relative to the U.S. war policy has made producers rather reluctant about booking business for definite delivery. Canadian manufacturers are affected to the extent that much difficulty is being experienced in the obtaining of raw materials and this circumstance is expected to become worse before it is better. Recent developments in the United States point to a re-adjustment of market conditions, more particularly in connection with copper which was recently brought into the limelight before the House of Representatives.

Pig Iron

The situation in pig iron remains unchanged, with the exception that prices on American iron are still advancing. The placing of orders for future delivery is not so pronounced as a few weeks back, but these lulls are generally a feature of such conditions as prevail at the present time. The supply of pig is still far below requirements of consumers, with the possibility that the situation may become still worse as the summer advances. The Canadian outlook is much the same, dealers looking forward to a stronger market than that now nominally quoted at $50 per ton.

Steel

The steel situation continues to reflect the increasing difficulties that are contingent on supplying unprecedented military, naval and domestic requirements. The rapid advance in prices does not appear to have had any effect upon the general demand; on the contrary, the consumption of raw material has gradually increased to such proportions that even with every possible facility working to highest producing capacity, the supply is inadequate to the needs of the trade. In many instances domestic business has had to stand aside in order that war necessities might receive the full attention of steel producers, but where domestic requirements could be handled, the high cost has only been a secondary consideration to that of securing material. However, both the Allies and the United States are fully impressed with the urgent necessity of sacrificing every non-essential need for the more rapid fulfilment of those demands that are directly or indirectly connected with the war. With these conditions developing, it is more than likely that still higher prices will require to be paid by contractors who desire material for strictly domestic purposes. The actual needs of the American Government are still a matter of conjecture, but it is reasonably certain that these requirements will gradually increase as the policy of the authorities assumes more tangible form. An undisputed fact appears to be that the full capacity of plate mills will be required for the accomplishment of the shipbuilding programme which is at present the centre of interest of an interesting and complicated situation, not alone on this side of the Atlantic, but in all European countries. The loss of tonnage has been so enormous that its replacement is probably the most essential factor in the problem now facing the various governments, and every co-operation should be made between producers and the governments, to further the speedy output of as much ship plate material as will meet all requirements of the shipbiulding industry. However, it is conceded that the past three years' experience has not been taken as an example, but more as a lesson, from which the future programme can be successfully prepared. The demand for shell billets of the larger sizes is less in comparison with that of a few months back, but the consumption of the smaller sizes shows no falling off. The Pittsburgh price on wire rods has been advanced $5 per ton, the quotation being now $100 per ton. This is the price on the open market, and is likely the result of the placing of a Government order of 25,000 tons, although it has not been announced what price has been paid. Structural steel is quite active, particularly in the States, where considerable tonnage is required for the erection of necessary additions to meet the increasing requirements. The sheet situation shows no improvement, and prompt shipment is practically impossible; the little available being secured by certain customers on the payment of large premiums. The Pittsburgh quotation on blue annealed sheets has been advanced $10 per ton, the base price being now 7½ cents per pound. Galvanized sheets are now quoted at $9.70 per hundred, the latest advance being $4 per ton. The situation in wrought iron pipe and boiler tubes is about the same, with the mills filled up for many months ahead. The market in wire products is expected to become stronger, following the recent advance in wire rods.

The situation in the Canadian market is much the same as last week, dealers holding to previous quotations, but with advances under consideration. Deliveries are becoming more uncertain owing to the developments in the United States.

Metals

The market in metals continues firm, but is influenced by the gradual development of war activities in the States, as uncertainty pervades the situation due to the fact that reliable information is not available regarding the definite war policy of the Government. Sensational statements relative to the actual production costs of copper has opened up a situation that may result in a complete revision of price quotations on all metals and also other products. Copper is still firm but with an uncertain undertone. Tin is quiet but fairly steady. Spelter has a firm tone but continues quiet. Lead is exceptionally strong with outside metal higher. Antimony is weaker abroad but firm locally. Aluminum is steady and unchanged.

Copper.—Somewhat of a sensation was created at a recent meeting of the American House of Representatives when it was learned that a current report of one of the largest copper producing companies in the United States, contained a statement that copper could be put f.o.b. the cars at 5¼ cents per pound. If this statement is true or reasonably so, the early future condition in the copper situation may develop some very interesting features. It has been intimated that further purchases of Government copper would be made at or around 25 cents, but the developments of the past week may upset the plans of the producers in making a market on a basis of their own. If investigation should prove that the above statement has been based on fact, it might apply also to other industries and a general re-adjustment would not be unlikely. The New York market is firm at present, but an undertone of weakness seems to pervade the situation.

Local dealers report unchanged conditions with prices firm but showing a weaker tendency, being 38½ cents for lake and electro, and casting 37½ cents per pound.

Tin.—The market has taken on rather a dull tone, and this is apparently accounted for by the uncertainty that prevails regarding the issuing of permits for tin shipments from England, together with the possibilty of loss in transit; the latter being a feature that tends to keep the market in somewhat of an unsettled state. Absence of activity is also due to lack of knowledge of what the attitude of the American Government will be, regarding the tax that is likely to be placed on tin in conjunction with other metals. With tin firm in London, the New York market shows a slight weakness, having declined ½ cent on the week, the current quotation being 65 cents per pound. The market here is unchanged, with prices steady at 62½ cents per pound.

Spelter.—With dullness featuring the present situation, the undertone of the market is comparatively strong, due to the fact that future positions are practically on the same level as spot metal. The whole situation is, however, influenced by the war arrangements, and until a definite programme is announced it is not expected that a sound market will prevail in this or any other metal. The quotation of 9⅝ cents per pound is ½ cent stronger than last week. In the local market an upward tendency is evident, but dealers continue to quote 13½ cents per pound.

Lead.—This metal appears to be the only one that is retaining its strong position without wavering, as in some respects it is the one that will have the heaviest demands made upon it when the final decision as to requirements is made by the American Government. Should the demand for excessive quantities be made suddenly, the supply would be quite inadequate to meet the need and prices in consequence would again soar. The "Trust" price remains firm at 10 cents, but "Independents" are asking as high as 11½ cents, this being ¾ cent higher than last week. Lead is firm locally at 13½ cents per pound.

Antimony.—The quiet tone of the market has developed a weaker tendency with the situation generally disturbed by the slow developments in U.S. Government circles. New York is quoting the nominal figure of 25 cents, which is one cent lower than a week ago. Dealers here are still quoting 27 cents, but on a quiet market.

Machine Tools and Supplies

The past week has seen a slight increase in the demand for machine tools, generally for fall delivery. This activity is along the lines of ordinary standard equipment for domestic purpose. The requirements for shell manufacture have shown considerable falling off, more particularly as regards the heavier shells; none of the machines used for the latter purpose, however, are being placed openly on the market as further production of the larger shells may only be deferred. The United States situation is unchanged, the trade apparently awaiting the outcome of the Machine Tool Builders Convention being held in Cincinnati. The attitude taken by this assembly will likely have considerable bearing on the future condition of the industry, as every feature of the general abnormal situation will receive the most careful attention, with a view to reasonable adjustment to suit the inevitable developments that are certain to follow an indefinite period of active participation in the war.

Scrap

The market is firm but uncertain and dealers are content to quote the prices that have prevailed for the past week. Dealers here report fair business, but handling of material is handicapped by lack of shipping facilities.

Toronto, Ont., May 29.—Manufacturers are feeling more than ever the shortage and high cost of raw materials while it is likely that a scarcity of labor will become more pronounced if conscription is enforced. As this is practically assured measures will have to be adopted to relieve the situation. In regard to the shortage of raw materials there appears little possibility of any betterment in the outlook. This is particularly true of iron and steel, as the demand for these materials is increasing out of proportion to the supply. The congestion at the mills is getting more acute with no prospects of production overtaking the demand. In spite of all these handicaps, trade was perhaps never better as shown in company reports and Government returns.

Steel

War requirements dominate the steel market to such an extent that every other consideration is relegated to the background and private consumers are in a worse position than at any time since the beginning of hostilities. The congested condition of the mills in the States is getting worse and the shortage of steel is thus becoming more acute. The constantly increasing demands of the American Government are making it increasingly difficult for private consumers of iron and steel to cover their requirements. Some of the larger makers of finished products have practically had to withdraw from the market owing to the fact that Government demands have to be met first. There is no let-up in the demand for steel products. Some concerns are said to be refusing business because of the crowded condition of the mills. Premiums are being paid for good deliveries and several steel concerns who can take contracts for comparatively nearby deliveries are receiving fancy prices from consumers who are in urgent need of material. Some consumers are sending in orders for steel without any reference to price. So urgent is the need that price is a secondary consideration. Warehouse stocks are also low, being in some cases depleted of certain sizes. Dealers are substituting sizes in order to meet customers' requirements. The situation is such that higher prices on steel products are inevitable. This week prices of iron and steel bars and small shapes have advanced 25c. per 100 lbs.; these materials being now quoted as follows: Iron bars 5c., steel bars 5.25c., and shapes 5.50c base. Steel plates have also advanced, but quotations are practically nominal. Plates, ¼-in. and larger, are now 9c., heads and tank plates, 9.10c. base. The situation as regards the supply of plates is getting tighter right along and prices continue to advance rapidly. Canadian shipbuilding interests who are in the market for plates are having the greatest difficulty in obtaining material even at the fancy prices now current. It is understood that approximately 75 per cent. of the plate mill capacity in the States is being used for shipbuilding. Wrought pipe is very firm at the last advance and higher prices are likely. Prices of boiler tubes continue very firm and heavy premiums are being paid to any makers of iron or steel tubes who can ship out fairly promptly.

Prices of black and galvanized sheets have again advanced and the market is very firm. Black sheets are now quoted at $8.60 for No. 20 gauge and blue annealed $8.15 for No. 10 gauge. Galvanized sheets have advance $1. Premier No. 28 being quoted at $9.70 and 10¾ oz. at $10. Canada plates bright are now $9.50 and dull $8.50. One reason for the advance in sheets is the high cost of sheet bars which have recently jumped up to $90 Pittsburgh. There is also a great scarcity of sheets as the American Government have taken over considerable tonnage. It is not unlikely that black sheets will be selling at $10 before the end of the year.

Arrangements are being made for the united buying of steel for the American and Allied Governments. By co-ordination in this way it is hoped that all available resources will be utilized to the best advantage. No prices have been as yet announced under the new arrangement, but it is believed that nearer current prices will be paid that were originally fixed. Prices continue to advance and it is evident that the market is still far from the turning point and that still higher prices may be expected. The chief problem for the steel mills to solve is the question of satisfying the enormous demands now being made upon them. The unfilled tonnage is piling up every day with no apparent possibility of overtaking the business. The shortage of steel is so great that consumers cannot obtain the required material and private enterprise is being interfered with. The principal price advances this week include semi-finished material. Bessemer and O.-H. billets and O. H. sheet bars are now quoted at $90 and forging billets $110 Pittsburgh.

Pig Iron

A leading domestic producer is practically sold up for this year and has booked considerable tonnage for delivery during the first half of 1918. Quotations are unchanged but firm at $50. The demand for pig iron continues heavy, but the furnaces, although operating at capacity, cannot cope with the situation. At Buffalo the market continues very strong with prices advancing. On foundry grades prices now range from $45 to $48 furnace for shipment over the remainder of the year; from $42 to $45 for shipment during the first quarter of 1918 and from $40 to $42 for shipment during second quarter.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the Commission headquarters are at Ottawa.

Scrap

The scrap market is firmer with higher prices on some old materials. Consumers who had been holding off buying owing to prevailing conditions have now come into the market to replenish stocks. This situation was expected and although as a result the market is firmer, it is still unsettled. Coppers, No. 1, composition and new brass clippings have all advanced, ranging from 1½ to 2c. Heavy melting steel is strong but unchanged. No. 1 machinery cast iron and malleable scrap have advanced $3 a ton.

Machine Tools

There is no change in the situation in regard to machine tools. Local machinery houses report fair business general on lines of machine tools, but no outstanding feature. Developments in the States, however, are being closely followed as the increased activity in the trade there will affect deliveries on imported equipment. Reports from machine tool centres in the States indicate that the trade is entering another period of great prosperity.

Supplies

Although there are no important price changes to note this week some advances may be looked for in the near future on account of the steady increase in cost of practically all raw materials. Current quotations are all very firm and business continues good. White lead has advanced and is now quoted at $17.50 per 100 lbs., in ton lots, with 30c. extra for less than ton lots.

Metals

While the non-ferrous metal markets are firm, the situation continues unsettled owing to the lack of definite information with regard to the American Government's requirements. On this account buying is not particularly active, the general disposition being to await developments. The American Government has appointed a sub-committee on pig tin, thus bringing it in line with other non-ferrous metals. This should do much to improve the situation in regard to this metal. Copper continues quiet, but prices are firm in expectation of heavy demand. Spelter is unchanged, but lead has advanced owing to scarcity of spot metal. The antimony situation is unchanged, but a decline in aluminum may take place as the American Government has fixed a price of 27½c. a pound as compared with 62c. prevailing in the outside market. Prices of solders have advanced due to the high cost of lead and tin. Business locally continues good with an upward tendency in prices.

Copper.—There has been no change in the copper situation and prices are firm at last week's level. It is not expected that there will be much change in the market until the American Government requirements are made known as to quantity and price agreement arrived at. It is, however, well understood that the Government needs will be heavy and also that the price will be pretty near the current outside market. The nearest copper which can be had just now from the leading producers is for July delivery, and there is very little of this now offering. Local prices are firm, lake and electrolytic being quoted at 37c. and castings at 36c. per pound.

Tin.—Although the market is a shade easier, prices are firm and underlying conditions point to renewed strength before long. The easier position in New York was due to freer arrivals of tin lately and a fair amount of metal on the way. Business has of late been quiet, there being a disposition to await developments following appointment of a sub-committee on pig tin by the American Government. Local price, 68c. per pound.

Spelter.—The market in New York is dull and unchanged. The trade is waiting to see what action the American Government may take in regard to their spelter requirements. The local situation is unchanged, spelter being quoted at 12c. per pound.

Lead.—The market is quiet but prices continue very firm. There is very little business passing on account of the scarcity of lead. The principal producers are out of the market and only lead that can be had is held by dealers who ask from 1c. to 1½c. above the "trust" price. consumers are holding off as long as they can. Lead has advanced ¾c. locally and is now quoted at 14c. per pound.

Antimony.—There is no change in the antimony situation. Arrivals have been absorbed and prices are firm on the basis of current quotations. that is, 30c. per pound.

Aluminum.—There is no change in the price of aluminum, although it is understood that the American Government have fixed a price of 27½c. per pound as against 62c. prevailing on the outside market. Local price unchanged at 68c. per pound.

Solders.—The high cost of lead and tin is forcing up rices of solder. Strictly is now quoted at 38c. and guaranteed at 41c. per pound, being an advance of 2c. Prices of Babbitt metals now range from 16c. to 65c. per pound.

Sydney, N.S., May 19.—Since the date of the last letter, the Royal Commission gave its finding in the matter of the wages of the employees of the Nova Scotia Steel & Coal Co., as follows:—"Ordinary laborers. 12½ per cent. increase; other classes, from $2.50 and under, 15 per cent. increase, including a number of hoisting enginemen; all classes from $2.50 to $3, 10 per cent. increase; all classes above $3, 5 per cent. increase; handpick miners, 7½ per cent. increase; shooters and loaders, 7½ per cent. increase; machine runners, 5 per cent. increase; to become effective May 7, and all bonuses to be put on a flat rate.

"This award is to continue to 31st December. 1917, and from year to year thereafter, until or unless two months' notice by either party before the expiration of any calendar year is given of intention to terminate the agreement."

The Commission afterwards proceeded to Springhill Mines, for the purpose of reviewing the increases offered there by the Dominion Coal Co.. with which the workmen were not satisfied. The Commission confirmed the company's offer, with some concessions in the matter of pillar getting rates. and the finding, as in the case of the Glace Bay and Sydney Mine Collieries. was accepted by the men as the basis of a settlement.

In the published report of the Commission to the Minister of Labor regarding the situation at the Glace Bay Collieries. the Commission states it was found that the causes of unrest were principally two, namely:—

"First, a feeling of discord resulting from the presence in the same field of two rival labor organizations. This feeling interfered in many ways with the successful prosecution of the industry in the different collieries, and produced widespread friction and irritation. The Commission was able to persuade the leaders of the two organizations to agree to the establishment of a new organization, which is intended to absorb the membership of the two existing ones, and we believe that in due course this scheme will be carried into effect to the advantage of both employers and employees, as well as of the community. The Commission gave its unqualified approval of the proposition.

Since the sittings of the Commission, the proposal for amalgamation of the unions has been favorably reported on at meetings of the different lodges, and it seems probable that amalgamation will shortly be consummated.

With the month of May, weekly pays are substituted for fortnightly pays at the mines of Nova Scotia, in accordance with legislation passed at the 1916 session of the House of Assembly. It is yet too soon to say what the effect on production will be. So far in May, outputs have been well maintained, and production will approximate more slosely to that of the corresponding month in the previous year than for a long time past. This is, however, partly due to the fact that it was about May. 1916, when outputs commenced to decline so very seriously.

A large amount of coal is being banked at the collieries because of the impossibility of obtaining ships to transport the coal to market. This has been occasioned by Admiralty requisition of the chartered ships of the Dominion Coal Co., and the practical impossibility of obtaining ships to replace them at freight rates which will make coal transportation commercially practicable.

CANADA'S TRADE BALANCE

WHILE the volume of Canada's trade with the rest of the world continued to show large expansion through the first four months of the present year, the expansion has been larger in what the country has been buying abroad than in what it has been selling. This will have been noted in a general way in connection with the April returns, which showed an excess of 21 millions in imports entered for consumption over exports of domestic produce, the first adverse balance reported for a good many months.

The total trade for the four manths of the year, leaving aside the gold figures and exports of foreign produce, was 683 millions, against 499 millions in the corresponding period of 1916. and only 267 millions in the corresponding period of 1915, increases of approximately 40 per cent. and 155 per cent. respectively. Of the gain of 184 millions, however, as compared with 1916, 115 millions fell under the head of imports, against a 69-million gain in exports. So while Canada in the first four months of 1916 built up a favorable trade balance of 71 millions, the favorable balance for the first four months of 1917 is down to 25 millions. This is still by long odds the most favorable showing for the period with the exception of 1916, comparing with adverse trade balances of as much as 122 millions in 1913. None the less it is a retrograde movement at a time when high prices for our agricultural output and huge orders for war supplies are being counted on to fortify the country's financial standing.

National Revenues

National revenues naturally continue buoyant under the large expansion in imports, Customs' collections in April, for instance, being $13,875,485, against $9,797,365 in April, 1916; but our interest obligations have increased with heavy outlays for war expenditure, and the main dependence for keeping the position steady, while the inflow of new capital for development is checked, rests in establishing and holding a favorable trade balance—in selling abroad a good deal more than we buy.

Comparisons of the trade record from January to April (four month periods) in each of the last six years follow:

Year.	Exports	Imports	Balance
1917	$354,891,404	$329,497,238	+ $ 25,394,166
1916	285,168,625	214,008,068	— 71,160,557
1915	131,286,747	136,045,451	— 4,758,701
1914	90,225,886	169,510,102	— 79,284,216
1913	99,119,323	221,795,966	— 122,676,643
1912	77,005,714	184,504,469	— 107,498,755

+Favorable balance; —Adverse balance.

Only for the sharp falling off in April exports the favorable balance for the four months of the current year would have made a showing approximately as good as that of a year ago. Exports and imports for the first four months of the year compare as follows:

1917.	Exports	Imports	Balance
Jan.	$ 99,106,259	$ 72,323,074	+ $26,783,185
Feb.	68,224,383	68,030,469	+ 193,914
March	122,415,313	102,335,886	+ 20,079,427
April	65,145,449	86,807,809	— 21,662,360
Total	$354,891,404	$329,497,238	+ $25,394,166

May Expectations.

It may safely be presumed that the sharp decrease in exports in April, as compared with March—they were only little more than half the March total—was due to shipping difficulties. The opening of navigation and the outrush of grain for Europe should result in very substantial gains in May export figures, at least under the head of agricultural exports. The grain is badly needed in Europe and ships must be found to carry it. The decline in the premium on New York funds in the past few days has already been noted as an indication that wheat is moving again in large volume.

April figures have never been particularly good in the matter of exports. Still, last year and also in 1915 Canada managed to show a small excess of exports over imports. Comparisons for six years follow:

April	Exports	Imports	Balance
1917	$65,145,000	$86,807,000	— $21,662,000
1916	55,092,000	50,147,000	+ 4,944,000
1915	28,691,000	28,391,640	+ 300,000
1914	17,753,000	36,937,000	— 19,184,000
1913	22,016,000	48,488,000	26,472,000
1912	13,676,000	45,607,000	31,931,000

The April exports in their usual classification compare with those of April, 1916, and of March, 1917, as follows:

	April. 1917	April. 1916	March. 1917
Mine	$ 3,859,510	$ 3,690,744	$ 9,980,711
Fisheries	648,336	829,515	2,373,258
Forest	2,461,312	2,287,939	3,614,385
Animals	5,511,691	5,112,105	14,809,941
Agricultural.	11,443,161	21,305,977	21,962,252
Manufac.	40,859,646	21,573,078	69,239,486
Miscell.	328,793	292,677	435,280

NIAGARA FALLS POWER CO. REPORT

THE pamphlet report of the Niagara Falls Power Co., for the year ending Dec. 31, 1916, says that all permitted means have been taken to meet the rapidly-increasing demand for power. Two additional generating units in the Canadian plant have been completed and placed in service. A third unit is now in process of being added. The management points out that the rapid increase in power use in Canada has led the Government to reduce considerably the permits for the exportation of Niagara power, and adds:—"The export license of our Canadian company has been reduced from 75,000-horsepower to 30,000 horse-power. We have, therefore been obliged to withdraw 45,000 horse-power from American industries, despite insistent demands."

INTERNATIONAL NICKEL CO.

The new $4,000,000 refining plant of the International Nickel Co., at Port Colborne, Ont., has all the foundations completed and the steel work on the main building finished. The first nickel will probably be turned out December next. The plant lies east of the entrance to the Welland Canal and has good transportation by rail and water. The initial output will be 15,000,000 pounds of refined nickel a year, with provision made for an output three or four times that amount. The operating force will be between three and four hundred men. Most of the construction supplies have been purchased in Canada. In operation, the plant will consume 100,000 tons a year of coal, coke, cordwood, fuel oil, nitre cake, charcoal, silica, rock salt, soda ash, soda nitrate, sulphuric acid, fire clay, and fire brick in addition to the copper nickel matte which will be supplied from the company's mines at Sudbury.

FOUNDRYMEN'S CONVENTION AND EQUIPMENT EXHIBITION

NEW ENGLAND foundrymen already are making extensive preparations for the reception and entertainment of the members of the American Foundrymen's Association and the American Institute of Metals, who will meet in annual convention at Boston during the week of Sept. 24. Concurrent with this great gathering of foundrymen will be held the yearly exhibition of foundry equipment and supplies, machine tools and accessories, in Mechanics' Building, which affords 80,000 square feet of floor space.

Never before in the history of these organizations has as much interest been manifested in this event, so far in advance of the opening date, as this year. Space reservations for exhibits already have been made by 80 manufacturers, and last year's total of 150 at Cleveland, promises to be greatly exceeded. The average space per exhibitor also shows a big increase over previous years and the indications are that Mechanics' Building will be crowded to capacity. A prominent feature of the Boston show will be the extensive display of machine tools. New England builders promise to be unusually well represented and numerous reservations also have been made by machine tool builders in the central west.

The Boston exhibition will be a great patriotic demonstration of the preparedness of equipment builders to meet the most exacting needs of foundrymen and machine shop operators in this great crisis. The labor-saving tools that will be displayed will demonstrate how operations can be speeded-up to meet the demands of the Government, and, in addition, engineers will be in attendance who will explain the intricacies of munitions manufacture.

The programme for the technical sessions of the American Foundrymen's Association is unusually complete, and provides for separate sessions for the discussion of grey iron, steel, and malleable iron topics. Three symposiums have been scheduled, namely, "Military Stores," "After-treatment of Castings to Improve Their Physical Characteristics," and "Refractories." The opening meeting on Monday afternoon, Sept. 24, will be a joint session of the American Foundrymen's Association and the American Institute of Metals. Throughout the remainder of the week, ending with Friday, Sept. 28, only morning sessions will be held and the same plan will be followed, which proved so satisfactory at Cleveland last year. It is probable that simultaneous sessions of the malleable and grey iron and steel sections will be held Wednesday, Thursday and Friday. The exhibition will be formally opened Tuesday morning, Sept. 25, and will close Friday evening.

Headquarters for the American Foundrymen's Association will be at the Copley-Plaza Hotel, although the meetings will be held in the Mechanics' Building. The American Institute of Metals will have its headquarters at the Hotel Somerset and its meetings will be held at this hotel or in the exhibition building.

The foundrymen of New England have completed a strong organization to provide for the reception and entertainment of the visitors. While their plans have been outlined only tentatively, the programme includes a boat trip around Boston harbor, theatre party, a visit to one of the big league parks to witness a professional ball game, ladies' luncheon and plant visitation. The complete list of committees appointed by the New England Foundrymen. follows:—

EXECUTIVE COMMITTEE.

W. J. Lavelle, chairman, New England Coal & Coke Co., Everett, Mass.
J. O. Henshaw, 79 Milk St., Boston.
C. A. Reed, Reed, Fears & Miller, Boston.
R. D. Walker, Walker & Pratt Mfg. Co., Boston.
W. E. Freeland, The Iron Age, Worcester.
A. R. Plant, Blackstone National Bank, Providence, R.I.
W. A. Viall, Brown & Sharpe Mfg. Co., Providence, R.I.
Fred F. Stockwell, Barbour-Stockwell Co., Cambridge, Mass.
A. B. Root, Jr., Hunt-Spiller Mfg. Corp., Boston.
T. R. Scott, Brown & Sharpe Mfg. Co., Providence, R.I.

RECEPTION COMMITTEE.

E. A. Tutein, chairman, Thomas Iron Co., Boston.
H. Paul Buckingham, Arcade Malleable Iron Co., Worcester.
H. F. Winlock, Barbour-Stockwell Co., Cambridge, Mass.
George H. Gibby, Gibby Foundry Co., Boston.
W. Scott Thomas., J. W. Paxson Co., Providence, R.I.
F. B. Farnsworth, McLagon Foundry Co., New Haven, Conn.
George A. Ray, Taylor & Fenn Co., Hartford, Conn.
H. W. Woodworth, American Tool & Machine Co., Boston.
Charles Van Stone, Lumsden & Van Stone Co., Boston.
D. D. Bartlett, Builders' Foundry Co., Providence, R.I.
F. W. Stickle, Capitol Foundry Co., Hartford, Conn.
Robt. C. Newcomb, Deane Steam Pump Works, Holyoke, Mass.

FINANCE COMMITTEE.

W. A. Viall, chairman, Brown & Sharpe Mfg. Co., Providence, R.I.
H. A. Carpenter, General Fire Extinguisher Co., Providence, R.I.
W. J. Breen, Wm. J. Breen Co., Boston.
A. N. Abbe, American Hardware Corp., New Britain, Conn.
A. R. Plant, Blackstone National Bank, Providence, R.I.
A. J. Miller, Whitehead Bros. Co., Providence, R.I.
W. C. Fish, General Electric Co., Lynn, Mass.
L. G. Kibbe, Turner & Seymour Co., Torrington, Conn.

LADIES' ENTERTAINMENT COMMITTEE.

R. D. Walker, chairman, Walker & Pratt Mfg. Co., Boston.
L. S. Brown, Springfield Facing Co., Springfield, Mass.
Charles L. Newcomb, Deane Steam Pump Works, Holyoke, Mass.
Robt. C. Bird, Broadway Iron Foundry, Cambridge, Mass.
Carl S. Dixson, General Electric Co., Pittsfield, Mass.
W. H. Coffin, Springfield Facing Co., Springfield, Mass.
J. F. Lanigan, Davis Foundry Co., Lawrence, Mass.
W. M. Saunders, Saunders & Franklin, Providence, R.I.

ENTERTAINMENT COMMITTEE.

C. A. Read, chairman, Reed, Pears & Miller, Boston.
W. T. Bennett, secretary, Griffin Wheel Co., Chelsea, Mass.
S. E. French, Athol Machine Works, Athol, Mass.
T. Officer, Sullivan Machinery Co., Claremont, N.H.
A. F. Crobin, Union Mfg. Co., New Britain, Conn.
H. A. Nealley, Jos. Dixon Crucible Co., Boston.
G. P. Aborn, Blake & Knowles Steam Pump Works, Cambridge, Mass.
C. A. Olson, Walworth Mfg. Co., Boston.
B. S. Leslie, United Shoe Machinery Co., Beverly, Mass.
T. R. Scott, Brown & Sharpe Mfg. Co., Providence, R.I.
Chas. V. S. Paul, R. Estabrook's, Sons, Boston.
Charles L. Nutter, Old Colony Foundry, Bridgewater, Mass.
C. E. Hildreth, Whitcomb-Blaisdell Machine Tool Co., Worcester, Mass.
E. B. Freeman, B. F. Sturtevant Co., Hyde Park, Mass.
D. F. Eagan, Hotel Seymour, Lynn, Mass.
D. F. Curtin, Waltham Foundry Co., Waltham, Mass.
A. L. Haasis, Jos. Dixon Crucible Co., Jersey City, N.J.

GOLF COMMITTEE.

J. O. Henshaw, chairman, 79 Milk St., Boston.
A. E. Blazo, Rogers, Brown & Co., Boston.
C. A. Wyatt, Debevoise-Anderson Co., Boston.
Thomas F. Stokes, Alley & age Co., Boston.

PRESS COMMITTEE.

W. E. Freeland, chairman, The Iron Age, Worcester, Mass.
A. W. Howland, The Foundry, 90 West St. Bldg., New York.
A. O. Backert, Cleveland.

POPULAR TAXATION.

We must learn by degrees the art of raising heavy revenue from taxation. To be effective, levies must be popular. American public opinion, peculiarly averse to taxes, can not be expected to change over night from a parsimonious attitude toward customs and levies to one of British or French unquestioning liberality.

France's budget for three months' war is announced at nearly two billions; it has excited no special comment in that country. The expenditure contemplated is proportionately equal to our own.

In December, 1915, the Chancellor of the Exchequer estimated the national wealth of the United Kingdom at seventy-three billions of dollars and national income was shortly after placed by Sir George Paish at fifteen billions. Revenue from customs, excise, income and other taxes for the year ended March, 1916, amounted to over two billions eight hundred millions.

It would be futile to attempt any proportionate revenue plan here. Our income is not similar,

Enlarged Canadian Trade Intelligence Service

Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department of Trade and Commerce, Ottawa, is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.

BRAZIL—Bahia, British Consul. Rio de Janeiro, British Consul General.

CHILE — Valparaiso, British Consul General.

COLOMBIA — Bagota, British Consul General.

ECUADOR—Quito, British Consul General. Guayquil, British Consul.

EGYPT — Alexandria, British Consul General.

FRANCE—Havre, British Consul General. Marseilles, British Consul General.

INDIA—Calcutta, Director General of Commercial Intelligence.

ITALY—Genoa, British Consul General. Milan, British Consul.

MEXICO—Mexico, British Consul General.

NETHERLANDS—Amsterdam, British Consul.

PANAMA—Colon, British Consul. Panama, British Vice-Consul.

PERU—Lima, British Vice-Consul.

PORTUGAL—Lisbon, British Consul.

RUSSIA—Moscow, British Consul General. Petrograd, British Consul, Vladivostock, British Consul. Odessa, British Consul General.

SPAIN—Barcelona, British Consul General. Madrid, British Consul.

SWEDEN—Stockholm, British Consul.

SWITZERLAND—Geneva, British Consul.

URUGUAY—Monte Video, British Vice-Consul.

VENEZUELA — Caracas, British Vice-Consul.

Canadian Commercial Intelligence Service

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

CANADIAN TRADE COMMISSIONERS.

ARGENTINE REPUBLIC—B. S. Webb, Acting Canadian Trade Commissioner, Reconquista, No. 46, Buenos Aires. Cable address, Canadian.

AUSTRALIA—D. H. Ross, Stock Exchange Building, Melbourne. Cable address. Canadian.

BRITISH WEST INDIES—E. H. S. Flood, Bridgetown, Barbadoes, agent also for the Bermudas and British Guiana. Cable address, Canadian.

CHINA—J. W. Ross, 13 Nanking Road, Shanghai. Cable address, Cancoma.

CUBA—A. T. Quilez, Acting Canadian Trade Commissioner, Lonja del Commerci, Apartado 1290, Havana. Cable address, Cantracom.

FRANCE—Phillipe Roy, Commissioner General, 17 and 19 Boulevard des Capucines, Paris. Cable address, Stadacona.

JAPAN—E. F. Crowe, Acting Canadian Trade Commissioner, P. O. Box 109, Yokohama. Cable address, Canadian.

HOLLAND—P. H. Geleerd. Acting Canadian Trade Commissioner, Zuidblaak, 26, Rotterdam. Cable address, Watermill.

RUSSIA—C. F. Just, Canadian Government Commercial Agent, Alexandrinskaia, Plosch 9, Petrograd. L. D. Wilgress, Canadian Government Commercial Agent, Bukhgolza Ulitza No. 4, Omsk, Siberia.

NEWFOUNDLAND—W. B. Nicholson, Bank of Montreal Building, Water Street, St. John's. Cable address, Canadian.

NEW ZEALAND—W. A. Beddoe, Union Buildings, Customs Street, Auckland. Cable address, Canadian.

SOUTH AFRICA—W. J. Egan, Norwich Union Buildings, Cape Town. Cable address, Cantracom.

UNITED KINGDOM—Harrison Watson, Sub-division E.C., 2, 73 Basinghall Street, London, E.C., England. Cable address, Sleighing, London. N. D. Johnston, Sun Building, Clare Street, Bristol. Cable address, Canadian. J. E. Ray, Central House, Birmingham. Cable address. Canadian. J. Forsyth Smith, 31 North John Street, Liverpool. Cable address, Cantracom. F. A. C. Bickerdike, 4 St. Ann's Square, Manchester. Cable address, Cantracom. J. Forsyth Smith, Acting Canadian Trade Commissioner, 87 Union Street, Glasgow, Scotland. Cable address, Contracom.

CANADIAN COMMERCIAL AGENTS

AUSTRALIA—B. Millin, Royal Exchange Building, Sydney, N.S.W.

BRITISH WEST INDIES—Edgar Tripp, Port of Spain, Trinidad. Cable address, Canadian. R. H. Curry, Nassau, Bahamas.

NORWAY AND DENMARK—C. E. Sontum Gruhbegd No. 4, Christiania, Norway. Cable address, Sontums.

SPAIN—J. F. Roberts, Care British Consulate General, Barcelona.

CANADIAN HIGH COMMISSIONER'S OFFICE

UNITED KINGDOM—W. L. Griffith, Secretary, 17 Victoria Street, London, S.W., England. Cable address, Dominion, London.

our assets are not similar and our viewpoint of taxes is not similar.

A large part of our dividends and interest is, in fact, industrial profit. In sharp contrast to the investment class of other countries, our investors operate the industries in which they are interested. Our "capitalists," as they are called, are in fact industrial workers, hard workers personally, and not by deputy. They have created the investments they own.

The assets from which these profits and wages are earned are largely immobile or at least slow moving. They have never been as yet properly appraised and are spoken of only in general and vague terms of many billions.

Even in times of peace the private income of the United Kingdom paid four times as much in national taxes as our own, counting customs as taxes. We are not as willing to pay taxes as our English cousins, because we have not been so much accustomed to them. Our income has been in earned wages and profits in the nature of wages from our business, which is to produce and manufacture and carry our products. Our enterprise calls for the active employment of all of our liquid capital most of the time.

To render taxation popular—to increase public willingness to raise revenue, Congressional appreciation of our distinctive economic cleavage is essential. Our capacity is an earning capacity. Taxation ought to be chiefly of our products, not of production.—Wall Street Journal.

CATALOGUES

Grinder.—The Webster & Perks Tool Co., Springfield, Ohio, have distributed to the trade a leaflet describing and illustrating their regular No. 1 grinder, floor or bench type. A specification giving the principal sizes is included together with list prices.

SKF Ball Bearings.—A pocket list of ball bearings issued by the Canadian SKF Co., Toronto, contains primarily a series of tables giving the dimensions, maximum loads and prices of different sizes of bearings covering all types. Other matter includes illustrations of radial and thrust ball bearings and also a brief description covering the constructional features of the SKF bearings.

BOOK REVIEW

Manufacture of Artillery Ammunition, by L. P. Alford, and associate editors of the *American Machinist*. 777 pages, 6 x 9 ins., and about 675 illustrations. Published by McGraw-Hill Book Co., New York city. Price $6. This book forms a convenient and interesting work of reference as well as a permanent record of munitions-making methods on the North American continent. The subject matter is divided into four sections: Shrapnel, high-explosive shells, cartridge cases, and fuses. Detailed descriptions of each operation, types of machines, and devices employed with output records, imparts more than a passing value to the accumulated data. Much of the information has previously appeared in the *American Machinist*, the efforts of the staff having been supplemented by a few contributors. The illustrations are excellent and profuse, working drawings being fully dimensioned wherever possible. An appendix of 30 pages includes notes on: Machine Tools for Munitions Manufacture—Composition and Properties of Shell Steel—Light Shells—Details of Some Shrapnels — Details of Some High Explosive Shells—British Requirements for Projectile Inspection, etc.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

ENGINEERING

Quebec, Que.—Louis Lavoie is building a machine shop here.

Winnipeg, Man.—The city will expend $60,000 on erecting new street lamps.

Windsor, Ont.—The Maxwell Motor Co. contemplate erecting a factory here.

Welland, Ont.—Electro-Metals, Ltd., will build additions to their plant, costing $50,000.

Three Rivers, Que.—The Three Rivers Casting Co. are building a foundry and forging plant here.

Toronto, Ont.—The William Davies Co. will build an extension to their boiler house on Front Street East at a cost of $6,000.

Montreal, Que.—The Howard Smith Paper Mills have under consideration the installation of a 11,000-h.p. hydro-electric unit at Crabtree Mills.

Renfrew, Ont.—The town has purchased the Renfrew Power Co.'s water rights, hydraulic and electrical equipment. The price was $100,000.

Niagara Falls, Ont.—The Niagara Falls Power Co. is installing a third generating unit, two having recently been completed and placed in service.

Port Arthur, Ont.—The Hennepin Mining Co., which was recently incorporated, will likely establish a smelter here. W. F. Langworthy is interested in the project.

Brantford, Ont.—An effort will be made to have a hydro-electric system installed here. A by-law was carried some years ago, but nothing further was done.

Brandon, Man.—The Brandon Machine Implement Works, whose plant was destroyed by fire over a year ago, are starting to manufacture a cultivator, and will probably enlarge their plant for this purpose.

Toronto, Ont.—The Hoyt Metal Co. have received a permit to build an addition to their factory on Eastern Ave., near the north-east corner of Lewis St., at a cost of $5,000.

Sidney, C.B.—It is understood that the Dominion Steel Corporation will start operations again at their rail mill. A considerable tonnage of rails is required for renewals for the Intercolonial Railway.

Winnipeg, Man.—Fire on May 16 destroyed the greater part of the buildings and equipment of the Winnipeg Foundry Co. The loss is estimated at $20,000, with only $4,000 insurance. J. H. Pace is president of the company.

Alliston, Ont.—The town, on May 21, accepted Hydro-Electric service by a vote of the people, which was practically unanimous. Two by-laws were submitted to the people. The response to the enabling by-law was unanimous, while the by-law to issue debentures to cover the cost of installation was given 280 affirmative and 3 negative votes.

GENERAL

Pembroke, Ont.—Fire destroyed the mills of the Colonial Lumber Co. last Monday, causing loss of $140,000. The origin is unknown.

Montreal, Que.—Construction work is under way on the erection of a factory the Montreal Box Board Co., to cost $20,000.

Chambly, Que.—Work will start shortly on the construction of a factory for the Canadian Leatherboard Co. G. B. Mitchell, of Montreal, is the general contractor.

Elmwood, Man.—The Stewart Sheaf Loader Co., will shortly commence the erection of a modern factory in Elmwood. The building which will have the latest appliances will be one story in height.

Peterborough, Ont.—It has been announced that the initial cost of the new plant of the Quaker Oats Co. will be $1,500,000. The main plant will be eight storeys high and will replace the structure that was destroyed by fire in December last. A by-law to authorize the construction of an overhead bridge and a smaller traffic bridge will be voted upon May 31st.

ELECTRICAL

Drayton, Ont.—A by-law will be submitted to the ratepayers on June 4th to raise $9,500 by debentures for a hydro-electric system.

Omemee, Ont.—The Hydro-Electric Power Commission has informed Emily Township Council that, consequent upon an agreement with the village of Omemee for the distribution of power for electric light, etc., in the village, and the erection of a sub-station for this purpose, they will be in a position to distribute power to farmers within a certain radius of the village.

CONTRACTS

Montreal, Que.—The Montreal Tramways Co. have awarded a contract to the Canadian Westinghouse Co. for a 12,500-k.w. steam turbo-generator for the power station at Hochelaga.

North Bay, Ont.—The tender for building the new toy factory has been awarded to Henderson Angus. The contract price was $12,975 and $10 per cubic yard for extra concrete.

Kincardine, Ont.—Tenders for the purchase of the rails and other material of the West Shore Railway were opened at a meeting of representatives of the interested municipalities held recently at Kincardine. The tender of the Ontario Hydro-Electric Commission was the highest and was accepted. For the track (including rails, fish-plates, spikes, etc.) the figure was $40 a gross ton; for the rails of Kincardine and along the right of way, $45 a ton; for the bolts out of track, $5 per cwt.; for spikes out of track, $80 per short ton; for fish-plates out of track, $45 per gross ton; for the structural steel, 5c. a pound. The poles and ties were not sold. It is roughly estimated that at these prices about $120,000 will be realized from the sale of the material.

MUNICIPAL

Wolseley, Sask.—The Town Council recently passed a $9,000 by-law providing for extensions to the municipal light and power plant.

Mitchell, Ont., ratepayers carried by-laws to issue debentures to improve the roads and to give a site and a fixed assessment to the Burritt Company.

Elmira, Ont.—The rate-payers voted on two industrial by-laws last Monday, one for a loan of $15,000 to the Machinery & Transmission Co., as an inducement to erect a large addition to their plant, and the other a small inducement to the Phonola Co. of Canada to commence operations in the Interior Woodwork Co. building. Both by-laws carried by the necessary two-thirds majority.

TENDERS

Three Rivers, Que.—The City Council are receiving bids on four turbine pumps, each having a capacity of between 2½ and 3 million gallons per day.

Paris, Ont.—The Town Council are calling tenders for a centrifugal pump with a capacity of 750 gallons per minute. Full particulars may be obtained from G. H. Armstrong, sec.-treasurer.

Trail, B.C.—Tenders will be received up to June 6 for work in connection with the extension of the waterworks system. Plans and specifications may be seen at office of W. E. B. Monypenny, city clerk, or at office of A. L. McCulloch, consulting engineer, Nelson, B.C.

Stratford, Ont.—Tenders will be received up to June 11 for furnishing and constructing a radial brick or concrete chimney and foundations for the refuse incinerating plant on St. Patrick Street, Stratford. Specifications and forms of tender may be obtained from the office of the city engineer, A. B. Manson.

Aikenhead's

"Van Dorn"

Portable Electric Drills Reamers and Grinders

THEY consume current only when working, and any lamp socket is a source of power. You will find hundreds of uses for them around your shop and they are dependable. Special fan-cooled Van Doron motor has 100% overload capacity. Van Dorn make-and-break switch acts so quickly that it practically eliminates the sticking and fusing of contacts. Phosphor bronze and ball bearing. Gears cut and hardened. All parts 100% oversize.

Do more work at less cost and they stay on the job.

Wahlstrom Automatic Chucks

Aikenhead Hardware Limited, 17 Temperance Street Toronto

Brampton, Ont.—Tenders will be received up to June 5 for the several trades required in the erection of a school building for the Brampton High School Board. Plans and specifications may be seen at the office of the architects and at the office of R. H. Pringle, secretary of the board, Dominion Bank Chambers, Brampton, Ont. Wickson & Gregg, architects, Toronto.

Toronto, Ont.—Tenders will be received up to June 5 for the sale and removal of four horizontal return tubular boilers from the west boiler room of the City Hall, Toronto. Copy of terms and conditions may be seen and tender form obtained, together with all information relative thereto, at the offices of the Property Department, City Hall.

St. Catharines, Ont.—Tenders will be received up to June 5 for one gasoline engine, 10-12 h.p.; two single-stage centrifugal pumps with valves, pipes, fittings and shafting; one electric motor and automatic starter. General plan and specifications and form of tender may be obtained from the office of W. P. Near, the City Engineer, St. Catharines, or from P. Gillespie, Engineering Building, University of Toronto, Toronto.

MARINE

Victoria, B.C.—A shipbuilding company has been organized here with a capital of $500,000. T. O. Cameron, of of the Cameron Lumber Co., is interested in the proposition.

St. Catharines, Ont. — The steamer Nipigon, bound up, carried away the two head gates of Lock 1, Welland Canal, on the evening of May 26, tying up navigation until the following night.

New Westminster, B.C.—It was reported that twenty-five wooden steamships will be built in British Columbia by the Imperial Munitions Board, and of this number probably eight will be built here.

South Vancouver, B.C. — Announcement was made at the meeting of the South Vancouver Board of Trade recently that a contract had been signed with the firm of Lamond & Harrison for the building of a wooden ship, 225 feet long, 44 feet wide and having a draft of 19 feet. The cost of the vessel will be approximately $225,000.

Victoria, B.C.—R. P. Butchart and Capt. Troup have arrived here from Ottawa with plans and specifications of the wooden ships that it is proposed to construct on the Coast. They will visit shipyards and possible sites for new plants. They are prepared to give contracts to builders who can demonstrate that they are in a position to fill them.

Vancouver, B.C.—The British steamer Ikeda of Vancouver, which was launched last month, is now formally registered from Vancouver, the papers having gone through at the Custom-house here a few days ago. The vessel was built at Stockton-on-Tees by Richardson, Duck & Co., Ltd., for the Union Steamship Co. of British Columbia, of which E. H. Beazley is manager. She is 410 feet long, 52 feet 7 in. beam, and 29 feet 5 in. deep. She is 4,760 tons net register, 9,935 tons displacement, and will carry 8,800 tons of cargo deadweight. She has 2,000 indicated horse-power, which give her a speed of ten knots, and her triple-expansion engines are 26, 42 and 70 by 48-inch stroke.

BUILDINGS

Toronto, Ont.—The Penfound Varnish Co. will build an extension to their factory at a cost of $1,400.

Cobourg, Ont.—Work has been started in transforming the old Customs building to a factory for the Bird-Archer Co., who are locating here. They will manufacture boiler supplies. Some of the machinery has arrived in town and is being installed. M. Jex & Co. have the contract.

PERSONAL

Alfred W. Smithers, chairman of the Board of Directors of the Grand Trunk Railway, is visiting Canada in the interests of the company.

Wm. Rodger, who has been chief draughtsman with the Jenckes Machine Co. of Sherbrooke, Que., for the past eighteen months, has accepted a position as construction engineer with Fraser Brace and Co., of Montreal, contracting engineers.

Antoine Balzola, president and secretary-treasurer of the Niagara Spanish Aerial Car Tramway over the whirlpool, had died suddenly at his residence at Niagara Falls, Ont., on May 21. He was the chief promoter and constructed the novel aerial car tramway over the whirlpool. His home is in Spain, and he was about 45 years of age.

Thomas J. Dillon, whose appointment as general manager of Canada Foundries and Forgings, Ltd., is announced, has heretofore had jurisdiction only over the western plants at Welland, Ont., the Canada Forgings and Billings and Spencer. This now extends to the James Smart Manufacturing plant at Brockville. Mr. Dillon, who is also one of the directors of the company, is one of the most successful forge managers in Canada, having been associated with the business for many years and virtually brought up in it.

Charles A. Hayes, who will succeed F. E. Gutelius as general manager of the Canadian Government Railway systems, has been acting as general traffic manager of the Intercolonial Railway, having joined that system when he left the Grand Trunk about four years ago. Mr. Hayes was born at West Springfield, Mass., in 1865, and is, therefore, in his 52nd year. He entered the railway service in 1882, and before joining the Grand Trunk was connected with several lines in the United States. He became manager of the National Despatch, Great Eastern Line, in 1902, and in 1903 was made assistant general freight agent of the Grand Trunk, which position he held for five years before he became general agent for the system.

INCORPORATIONS

The National Abrasive Co., has been granted an Ontario provincial license to manufacture abrasives of all kinds at Hamilton, Ont., with a capital not to exceed $60,000. J. Ross Ritchie of Toronto is the company's attorney.

Canadian Des Moines Steel Co., has been incorporated at Ottawa with a capital of $100,000 to acquire and take over the Chatham Bridge Co., of Chatham, Ont. The incorporators are R. L. Brackin, B. L. Bedford and E. W. Reeve all of Chatham, Ont.

The Wheel & Foundry Co., has been incorporated at Ottawa with a capital of $25,000 to carry on the business of iron and steel founders, engineers etc. The head offices are at Toronto, and the incorporators are A. T. Thomson, W. S. Morlock and R. H. Parmenter all of Toronto.

Dale Engineering Co., has been incorporated at Ottawa with a capital of $40,000 to carry on the business of a construction and Contracting Co., at Toronto. The incorporators are Samuel R. Birch, John F. Lennox and Harry C. Moore all of Toronto.

The McCord Mfg., Co., has been granted an Ontario provincial license to manufacture motors, engines, and machinery of all kinds. The capital is not to exceed $50,000 and the company's attorney is A. R. Bartlet of Windsor, Ont.

Wells Bros. Construction Co. of Canada Ltd., has been licensed at Toronto to construct and erect buildings and carry on a general contracting business. The capital of the company is not to exceed $20,000. J. T. Purvis of Toronto is the company's attorney.

Dominion Molybdenites Ltd., has been incorporated with a capital of $1,000,000 at Toronto to acquire and develop mineral lands and deposits. The head office is at Toronto and the incorporators are Kenneth A. McRae, William J. Lockwood and Kenneth McKay all of Toronto.

The Republic Stamping & Enameling Co., have obtained a provincial license to establish and operate a general stamping and enameling business. The capital of the company is not to be greater than $40,000, and the attorney is Charles H. Ivey of London, Ont.

Goderich Drydock & Shipbuilding Co., has been incorporated at Ottawa with a capital of $1,000,000 to carry on a shipbuilding business and make machinery appliances and engines etc., at Goderich, Ont. The incorporators are David T. Grant, Mervil Macdonald and P. E. F. Smiley, all of Toronto.

Edwin S. Woods & Co., has been incorporated at Ottawa with a capital of $40,000 to manufacture railway supplies, engines, boilers and machinery of all kinds at Montreal. The incorporators are L. A. David, L. P. Grepeau and S. H. R. Bush all of Montreal.

Hamilton Cotton Co., has been incorporated with a capital of $1,000,000 at Ottawa to carry on the business of cotton and flax spinners and linen manufacturers at Hamilton, Ont. The incorators are A. V. Young, J. V. Young and William Armstrong all of Hamilton.

Shipbuilders' Corporation Ltd., has been incorporated with a capital of $250,000 to construct ships, tugs, lighters, etc., of every description. The head office of the company is at Toronto and the incorporators are Gerard Ruel, Reginald H. M. Temple and R. G. O. Thomson all of Toronto.

RAILWAYS—BRIDGES

Toronto, Ont.—Manager Fleming of the Toronto Street Railway Co., has stated that an order has been placed for 100 new street car trucks, to be delivered before the end of this year. This is to fulfil the order of the Ontario Railway Board to provide 100 new cars this year and 100 next year.

TRADE GOSSIP

Winnipeg., Man.—The Swift Canadian Co., will extend their packing house here at a cost of $5,000.

Winnipeg, Man.—The Canadian Bag Co., will build an addition to their factory here to cost $31,000.

The Prest-O-Lite Co., Inc., have removed their Canadian general offices from Merritton, Ont., to the C. P. R. Bldg., Toronto. Cylinders are still being received and refilled at, and shipped from, Merritton, but all the general business of the company will be conducted from Toronto.

U.S. Steel Corp. to Build Shipyards.—The United States Steel Corporation has purchased a big acreage near Newark, in the New Jersey meadows, within a short distance of deep water, and will erect immediately a large shipyard where standard 8,000 and 10,000 ton steel ships will be constructed, probably with the co-operation of the Government Shipping Board.

Government Railways Mileage.—A big mileage is now under Government ownership and operation. The Transcontinental has 2,009 miles; Intercolonial, 1,562; Prince Edward Island Railway, 275; St. John Valley Railway, 205; and the International Railway of New Brunswick, 112 miles This makes a total of 4,163 miles operated by the Dominion Government.

The Canadian Car and Foundry Co. has closed an order with the Canadian Government Railways for one thousand freight cars and work on the order will be commenced at once. At the Lachine plant, at the present time one thousand cars for the French Government have just been completed and the first shipment will be made in the next few days, besides this, two thousand cars are under construction for the Russian Government.

Russian Platinum Production.—According to the British Consul at Ekaterinburg, Russia, the 1916 output of platinum in the Urals amounted to 86,500 troy ounces, only about three-fourths of the output in 1915. The chief causes of the decline in the production of platinum are the shortage of labor, the difficulty in obtaining spare parts for dredges, and the exhaustion of the richer alluvial deposits. New alluvia will undoubtedly be found when extensive prospecting is resumed.

Russia's Car Orders.—Russia's Car requirements, which have been talked of for over a year, are given a better standing by the American Government's loan to Russia. Car builders, according to the *Iron Age*, now expect the orders will be for 10,000 to 20,000 cars of 40,000 pounds capacity. Domestic car orders of the week amounting to 1,500 and 2,000 cars have been placed in Canada. New locomotive contracts total 500, and the two leading builders are well booked for months ahead.

Record Zinc Output by Smelters.—Advices have been received in Toronto from the Trail Smelter of the Consolidated Mining & Smelting Co. of Canada that the zinc refinery output has risen within the past few days to a new high record at 89,000 pounds, or equivalent to about 44½ tons. Last week a new record was created with an output of 83,000 pounds which has now been displaced. This development which is highly satisfactory to the board of directors, and should be to the shareholders, compares with a contemplated maximum output of 25 to 30 tons per day when the company undertook the production of zinc by electrolytic process.

Metal Market in New Zealand.—According to the latest published report, the metal market in New Zealand is very greatly restricted for lack of supplies, although there is not the demand for metals in general that obtained before the outbreak of the war. Building and public improvements have been curtailed materially during the past three years. There has been a fair demand for fencing and barbed wire, however, and the supply has become almost entirely exhausted. One firm reported late sales amounting to 180 tons of fencing and barbed wire received from manufacturers in the United States. This demand is liable to continue until the close of the war.

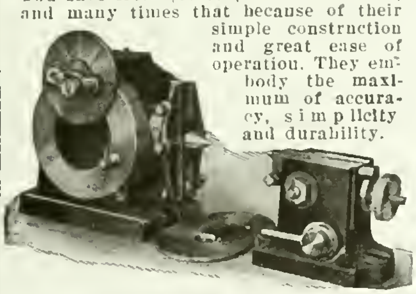
Purchasing Pool for Allies.—A Washington dispatch says that a program under which the American Government virtually would pool its purchasing for the sake of attaining maximum efficiency, with that of all the Allies, construct a buying machine into which hundreds of experts in many lines would fit as cog wheels, and place one man in charge of the whole gigantic enterprise, is under consideration and fast assuming definite outline. This man would be the world's super-buyer. Into his hands the nations at war with Germany would place approximately $10,000,000,000 a year, a store of money with no parallel in modern history. To assist this bureau head there would be an army of expert buyers familiar with the American markets, and selected for their ability.

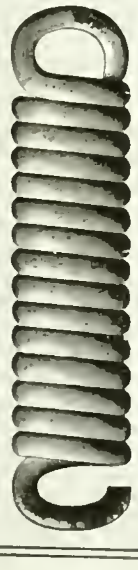
Trade Increase For April.—Canada's trade during the month of April totalled $157,320,000. Hon. J. D. Reid, the Minister of Customs, announced recently. The figure for the same month of 1916 was $106,585,000. There were considerable increases both in exports and in imports. The exports of domestic products reached $65,145,000, or $10,000,000 more than in April of last year, and included: Manufactures, $40,000,000; agricultural products, $11,000,000; food products such as meats, $5,500,000; minerals, $3,800,000; lumber, $2,500,000. Imports amounted to $86,000,000, comprising $42,000,000 worth of goods, admitted free of duty and $44,000,000 worth of dutiable goods. The sum collected in customs duties was $13,875,000, as compared with $9,000,000 in April, 1916.

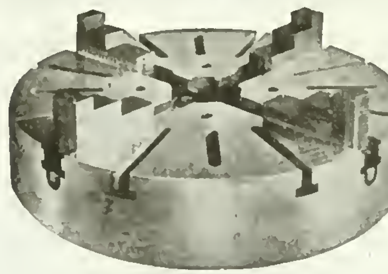
Record Demand for Steel Predicted.—Manufacturers who were present at the meeting of the American Iron & Steel Institute recently in New York were all of one opinion—that while capacity was larger than ever before, the demand was also record-breaking, and that the wants of consumers this year could not be satisfied. One of the largest subsidiaries of the U.S. Steel Corporation has notified consumers that it can make no further contracts until 50 per cent. of the orders now on the books are worked off. Many consumers want to buy steel for delivery as far forward as 1919. The steel companies will be the heaviest war tax payers this year, and the incomes of shareholders will be greatly increased. This will mean additional revenue for the Government. Steel manufacturers have been assured that nothing will be done in the way of price fixing for Government needs that will disturb their business in the least.

To Develop Canada's Fuel Supplies.—A resolution was adopted in the House at Ottawa recently reading as follows: "That in the opinion of this House, it is of great importance that the increasing demand for fuel for manufacturing and residential purposes be supplied in larger quantities and at cheaper rates than are now possible; that the deposits of bituminous and anthracite coal in Canada, located in the extreme eastern and western portions thereof, be more fully and thoroughly utilized for the benefit of the residents of the central Provinces; that the enormous peat and lignite deposits so widely distributed through all portions of the Dominion be also scientifically made use of for the same purpose, and further, that the Government of Canada make a special effort, through legislation and otherwise, to have these valuable deposits more fully and rapidly developed, to the end, that the people of Canada may be adequately provided with these fuels for industrial and residential purposes."

Wooden Ships for B.C.—The following is a description of the vessels that will be built in British Columbia, in an official statement issued by the Imperial







Munitions Board's representatives: 250 feet long, 43 feet 6 inches beam and 25 feet deep, with a dead weight capacity of about 2,800 tons on a draft of 21 feet. The vessels are to be built very strongly with box girder keelsons. They have a deep tank forward for water ballast. They are to be propelled by steam with triple-expansion engines of about 950 indicated horse-power. The matter of geared turbines from England is being considered for some of the ships. The vessels are to be built of Douglas fir to Lloyd's requirements for A1 classification. The system under which these vessels are to be built is as follows: The builder provides the shipyard and equipment; the board supplies standard plans and specifications, provides for a supply of all materials and for the machinery, and pays the contractor a stated margin of profit over actual cost of building. A uniform scale of wages.

CATALOGUES

Cooling Water For Ice Plants.—Bulletin dealing with economy cooling circulation water for ammonia or steam condensers by the method of spraying. Issued by the Spray Engineering Co., Boston, Mass.

Electric Tools.—The Stow Manufacturing Co., Binghamptom, N.Y., have issued two new miniature bulletins Nos. 101 and 102 dealing with their line of electric tools and flexible shafts. They have been issued in addition to the regular bulletins and are a distinct novelty owing to the small size and completeness of detail.

A Treatise on Milling and Milling Machines, published by the Cincinnati Milling Machine Co., Cincinnati, Ohio.—The idea of publishing this treatise was to place in the hands of those interested in and responsible for efficient production on milling machines, a more complete knowledge of the action of milling machines and the construction of different types of milling fixtures and holding devices, etc. The company have carried out some very exhaustive experiments in cutter designs, cutter and work cooling and other features which have led to marked improvement in the operation and design of milling machines. These developments have been compiled in complete form, in this book, and being in one volume will be more easily followed, and thus of greater service to the milling machine operator. A more complete knowledge of the action of milling cutting, a familiarity with different constructions and types of milling fixtures, the cause of unsatisfactory milling machine performance, etc., are all necessary for the intelligent operation of the present day milling machine. Considerable space has been devoted, in the 21 chapters which the book contains, to the various phases of these subjects, and new matter, never before published, has been included. The book contains 409 pages and 268 illustrations, while in addition there are a large number of rules, formulae and tables which will be extremely useful for the milling machine operator.

INDEX TO ADVERTISERS

The Dominion Forge & Stamping Co Limited.

Walkerville, Ont.

Staff Article

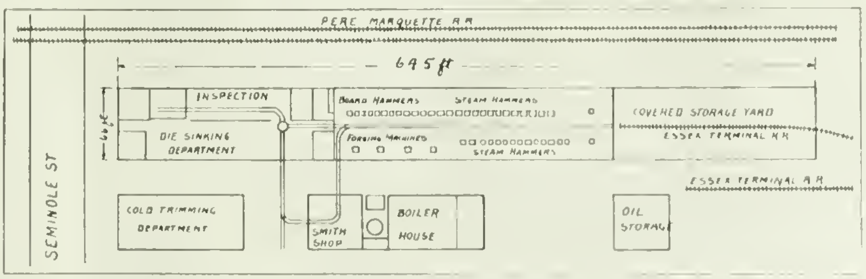
Next to the production of iron and steel from the raw ore, the field of operation covered by stamping and forging is of greatest, though not always most obvious importance. Recent events have tended to thrust machine shop work more into the limelight, but as a basic branch of engineering activity the art of stamping and drop forging may be expected to increase in importance as conditions revert to normal in the hoped-for near future.

NEXT to the production of raw material, the working of it into a semi-finished state suited for consumption by manufacturing plants, is perhaps the most important step in its progress toward the final consumer. Because of the nature of the work, and conditions of the business, drop-forging and stamping, to be successfully carried on, must be conducted with a degree of efficiency, both from an economic and productive point of view, exceeding that which is permissible in ordinary metal-working establishments. Occupying as it does, an intermediate stage between the initial and final stages of manufacture, the functions of a plant such as described in this article, must be discharged systematically and reliably, otherwise the successful operation of other plants dependent on its product may be seriously jeopardized. The growth of drop-forging and stamping work in this country has been steady and continuous over a number of years, and the magnitude of operations and extent of equipment installed serve to convey some idea of the important part played by firms of this type.

Plant Locations

The Dominion Forge & Stamp Co., Walkerville, Ont., operates two plants. The original plant, No. 1, adjoins the Grand Trunk Railway near Walkerville station and occupies the entire end of the block between St. Luke's Road and Albert Street. Both forging and stamping operations were carried on here until increased business made imperative the separation of the two branches, and accordingly a complete new forge shop was erected, being known as plant No. 2. It is also in Walkerville, on the line of the Pere Marquette Railroad, with office entrance on Seminole street.

Plant No. 1 is therefore entirely employed in the production of stampings and cold press work. Nearly all of the stamping work is in connection with the automobile business and consists of sheet metal fenders, tanks, mufflers and hoods. Some time ago, operations were extended to include the manufacture of automobile frames, and developments in this line have been such that arrangements are now being made to double the shop capacity for this product. Frame production is carried on in a separate building on the opposite side of Albert street, an interior view of this building forming one of the illustrations. Situated here is also the boiler house which was necessary for the original forge department before removal to plant No. 2, and which is now used for the central heating plant for the stamping division.



PLAN VIEW OF FORGE PLANT SHOWING LAYOUT OF DEPARTMENTS

Stamping Plant

The main building consists of four floors with basement and is of reinforced concrete construction with large lighting areas on all sides. It is 55 feet wide by 157 feet long. Extending to the rear is the tool room building, of single floor construction, connecting with the fender forming department. This latter department is parallel with the main building, and can be seen in illustration on page 580, where the monitor roof shows above the tool rom.

Press Room

The basement is devoted entirely to storage of raw material, many tons of sheet metal of various sizes and gauges being kept in stock, although present conditions of the steel industry and heavy demands for product have prevented any extensive accumulation of material. The first floor contains the receiving and shipping department with elevator service to all floors. All heavy stamping work such as blanking, flanging, etc., involving the use of large machines is done on this floor, a view of some of the larger presses being given on page 580. Five large double-crank presses are employed for blanking and forming sheets for automobile fenders, of which several types are made; flanging and embossing or doming over large areas is also done in these presses. Two of these large presses are shown toward the right of illustration. Additional equipment on this floor includes medium power presses and shears. Prominent amongst the makers of these machines are noted, the Toledo Machine & Tool Co., and the Consolidated Press & tool Co.

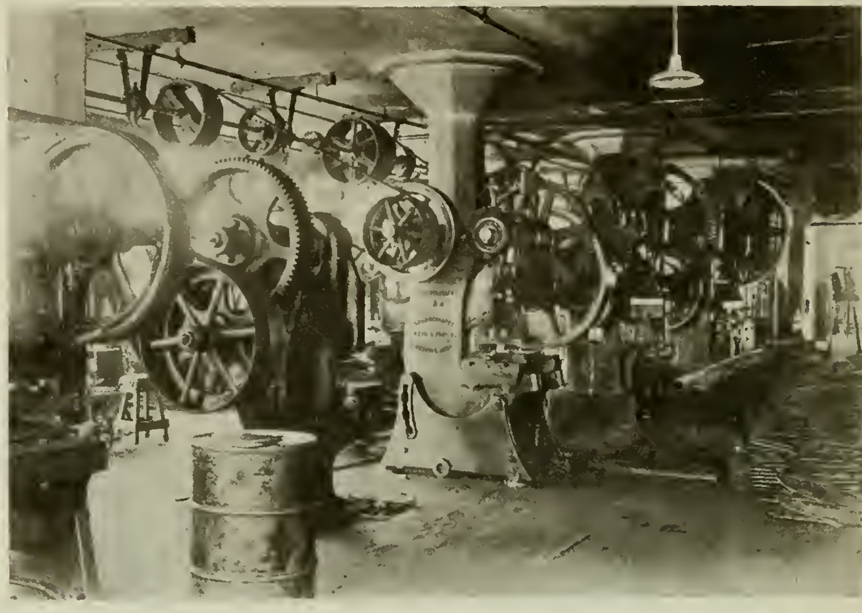
Fender Forming

Following the fender blanks to the forming department, the operations necessary to complete the crowning are done in a large double-crank press, after which the aprons, skirts, or fillers, as they are variously termed, are united with the fender proper by means of rolling and beading, these operations being done on special types of sheet metal working machinery. Some slight amount of hand work is necessary to remove variations in shape and any irregularities which occasionally appear, due to slight variations in the material being operated on.

Miscellaneous Assembly

Returning to the second floor of the main building—this is occupied with the assembling of muffler parts, engine hoods, tanks, etc., the equipment consisting of presses, shears, etc., such as are ordinarily used for such work. The third floor is occupied by the fender finishing department, which includes the fitting of reinforcements at different parts of the fenders, and the securing in place of various details either by beading and rolling or by electric welding. Final fitting by hand to duplicate fixtures representing the parts of the car frame, completes the work of fender making, which is followed by the enameling process before the fenders are complete and ready for shipment.

The locating of the enameling department on the fourth or top floor is desirable because of the freedom from the dust on the sheet, and the absence of annoyance to other floors by the presence of vapors and odors. The fenders are first of all cleaned with emery cloth after which they are washed in gasoline to remove all grease and foreign matter, The enamel is applied by dipping, the fenders being immersed in a large tank of liquid enamel and hung up to drain thoroughly before baking. Several coats are applied according to specification, each coat being baked at a temperature of 350 deg. F., in order to obtain that hard glasslike finish which is such a conspicuous feature of modern automobiles.



VIEW OF PRESS ROOM IN MAIN BUILDING. SHOWING TYPES OF MACHINES USED IN MAKING FENDERS.

Plant Maintenance

The construction and maintenance of stamping machine equipment calls for considerable experience in work of this class. The designing, building, and trying-out of a set of dies for a new design of fender is always a prolonged and expensive job. Methods which have been successfully applied in one shop may, for some unaccountable reason, fail to give satisfactory results in another, and the necessity of meeting the call for deliveries puts the job up to the tool room squad on their own merits, as it is generally preferable to find a way of doing the work in a satisfactory manner, rather than spend the same or longer time finding out why the other fellow's method will not work. It is not surprising, therefore, to note the extent of the tool room equipment, when one considers that, although the types of fenders produced are comparatively few, there are perhaps twelve to sixteen separate and distinct operations in each fender.

MAIN BUILDING OF PLANT NO. 1. WHERE HEAD OFFICE OF COMPANY IS LOCATED.

Prominent amongst the machines is a No. 6 vertical Becker milling machine, capable of handling a large variety of work in connection with the stamping dies. Three shaping machines are installed—C. M. C., Smith & Mills, and American Tool Works Co. Other machines include a large surface grinder for die-blocks, etc., built by the Safety Emery Wheel Co., a Le Blond tool room grinder, a Gray planer, and a Cataract bench lathe, the equipment being rounded out by such items as two milling machines (plain and universal), two sensitive, drills two vertical drill presses, one radial drill and three tool room lathes.

A blacksmith shop and heat-treating department are also provided, while a 9 x 8 in. motor driven Ingersoll-Rand compressor supplies high pressure air throughout the building.

Frame Manufacture

The frame shop, to which reference has already been made, is single floor brick building equipped for the quantity production of automobile frames. Operations at present are concentrated on two designs, the finished cars of which they are a part being two of the most popular makes in this country. Roughly speaking, the work of making a frame consists of shearing, trimming, punching, forming, assembling. The stock is received in sheets which are cut to the proper outline on a 12 ft. Niagara shear. Special trimming work is now done on the ends if necessary, according to the type of frame being made. This work consists of shaping the ends so that projecting lugs may be bent sideways at a later stage to form angle brackets wherewith to facilitate the assembling of the cross members with the sides.

The strip from which the side is formed, still flat, is now taken to a multiple punching machine which punches every hole in the side simultaneously. The machine is of special design and is located in the left background of the frame shop (see photo below). It is of the inverted type, with the lower platen operated by three eccentrics located underneath, the eccentric shaft and driving motor being all below floor level, so that the platen is at a convenient height for the operators to handle material. Eight massive steel columns threaded at their upper ends, support the stationary platen and provide adjustment for the various dies. This press runs approximately 10 strokes per min., and punches from 60 to 80 holes, round, square, or oval, at one stroke.

After a sufficient number of parts have been punched, the machine is changed over to forming work and turns over the top and bottom flanges which impart the familiar U section to the piece. Various other presses to the number of fourteen have meanwhile been engaged in similar work on the cross members, some of which are shown on trucks in the view of the frame room. These are now grouped together and riveted, some of the riveting being done in punch presses cold and some of it by pneumatic hammers hot.

In this building is also located the welding department in which two Prestolite welding outfits are installed. Much of their work consists in welding muffler parts and special exhaust pipe sections. Another 9 x 8 in. Ingersoll-Rand compressor is installed here for the pneumatic apparatus.

Considerable as is the output of this department, the constant growth of demand from the ultimate consumer has rendered necessary the doubling of capacity, and active operations are now in progress to duplicate the department, space being conveniently available at one end.

LOOKING DOWN THE CENTRE OF FORGE DEPARTMENT, PLANT NO. 2.

Forging Plant

The "Forge," as plant No. 2 is familiarly termed, is an excellent example of specialized plant design. While the conditions which prevailed in the original plant before the erection of these works delayed development of this line to some extent, it afforded desirable opportunity for studying the requirements and planning the arrangement of the new plant on the most efficient lines. The straight line design of plant has been adhered to in very complete degree, as with the exception of certain types of forgings which pass through the cold trimming department, the great bulk of the work passes continuously from storage shed into forge shop, thence to inspection, and finally shipping.

A study of the plant lay-out on page 579, combined with the title illustration, conveys a clear idea of the plant. The view forming the title is taken from Seminole street, just above the tracks, the forge shop occupying the main central portion of the building, with the steel storage shed showing at the far end. This shed is approximately 185 ft. long by 66 ft. wide, which is the uniform width of the main building. Both the storage shed and forge shop buildings are of considerable height in order to provide headway for a 5-ton Northern overhead traveling crane of 40 ft. span, which travels the full length of the two departments. A standard gauge spur track from the Essex Terminal Railroad extends the full length of the storage shed, so that incoming cars of raw material can be placed in close proximity to the particular section of storage space devoted to any certain class of material.

Routine of Operations

An industrial track system connects the various parts of the plant. Bundles of bar stock are deposited at the two Bertram bar shears, one on each side of the forge shop, where they are cut to the required length, while if no cutting is required, the traveling crane conveys the stock direct to the particular furnace, where it is to be forged. Passing along the forge shop, as shown in view above, on the right is a battery of Massillon steam hammers, consisting of four 1,500 lbs., and two of 2,500 lbs. capacity. The heavier sizes handle parts for railroad cars, such as draw-hooks, equalizing levers, spring shackles, etc. A number of motor car forgings are also produced at this point, steering knuckles, hand levers, etc., being prominent items.

Immediately across the shop from

COMPONENT PARTS OF AUTOMOBILE FRAMES IN PROCESS OF MANUFACTURE IN FRAME DEPARTMENT.

these is a battery of eight hammers, one 5,000 lbs. Chambersburg, and seven Massillon hammers, 1 of 3,000 lbs., 4 of 1,200 lbs., and 2 of 800 lbs. Crankshafts for motor car engines, front axle forgings, and various pieces of similar proportions, are forged on the larger hammers, while small parts, such as forked rod-ends, steering levers, etc., constitute the bulk of work done on the four smaller hammers.

Beyond the hammers on the right are nine board hammers engaged on munitions stampings and similar work, including one 1,500 lbs. Toledo, and eight Waterburys, from 800 to 1,000 lbs.

Forging Machines

The blocking out of certain types of forgings before going to the hammer is frequently desirable, the ends of front axles being an instance of this work, which is performed on forging machines of the Ajax, Acme and National types, having capacities for handling stock from 1½ in. to 4 in. Individual motor drive is installed on these machines, their location being opposite the board hammers.

Cold Trimming

Where the size and type of forging render it desirable, provision is made for hot trimming in a suitable machine placed next the hammer, but much small work can be trimmed to advantage when cold. The economy of this is apparent when it is considered that cold trimming is limited only by the speed at which the operator can feed the machine, whereas hot trimming is limited to the speed at which the hammer finishes the work; in addition to which the class of help necessary for cold trimming is comparatively unskilled compared with that of a drop-forge operator. The location of the cold trim shop is indicated in the plan and a view of one side is shown below. The bins at left are built with hopper bottoms, which cause the pieces to slide to the opening as quickly as they are withdrawn. An inclined runway extends from the yard to the top of the bins so that forgings can be dropped into the bins by the barrow load. Six Toledo presses are installed in this department, of the type shown in view.

Inspection

Forgings from the cold trim shop are now conveyed to the inspection room, where they rejoin the bulk of the work coming direct from the forge shop. Here the work is gone over carefully, being tumbled in barrels, dressed off in grinders, or otherwise manipulated, according to requirements, before being finally inspected and passed for shipment. Machine equipment in this department includes a set of Massillon shears, and two Newton motor-driven cold sawing machines.

DIE-SINKING DEPARTMENT, SHOWING TYPES OF MACHINES EMPLOYED IN PRODUCING DIES FOR THE HAMMERS.

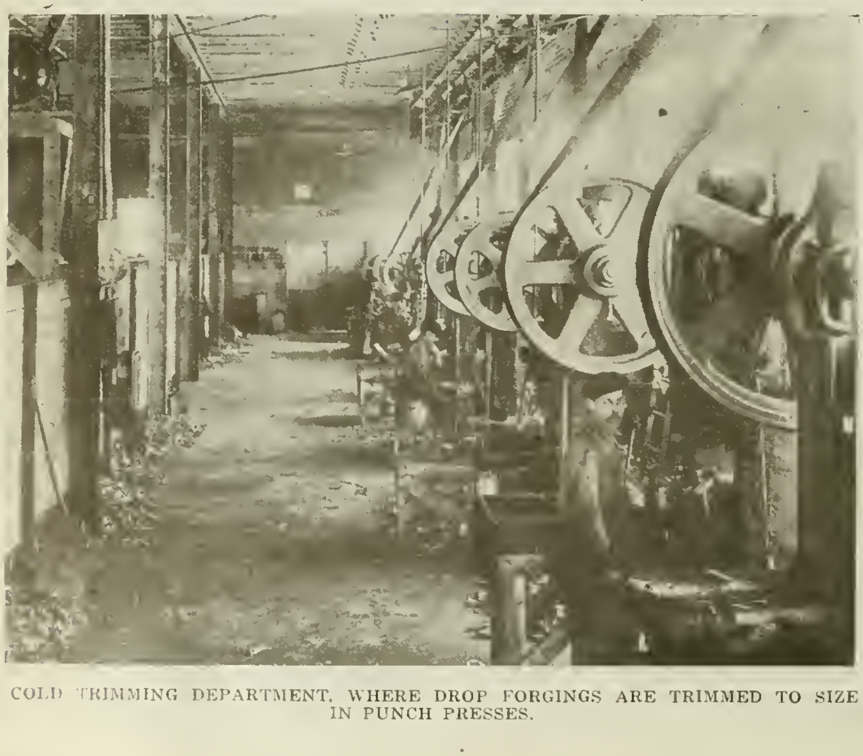
Die-sinking Department

The section of the main building in which the inspection department is located, also includes the die-sinking department and the office, with minor accommodation, such as tool crib, die storage, electrical department, machine repair, and locker space. The die-sinking department occupies almost half of the section which is 200 ft. long by 66 ft. wide. The equipment installed here is typical of modern practice and includes three Becker and four Pratt & Whitney vertical milling machines; one 12 ft. American, and one 10 ft. Pond planing machines; one Safety Emery Wheel Co. surface grinder; one 24 in. LeBlond lathe, one New Haven lathe, drilling machines, and shapers, the latter including four Gould & Eberhardt and one Hamilton.

Power Equipment

The remaining group of buildings contains the blacksmith shop and power department. The former is equipped principally for the work of hardening dies for the hammers and presses, four large furnaces being installed for this purpose. They are equipped to burn both gas and oil. Large quenching tanks containing brine, oil, etc., are provided for cooling purposes. A 1,500 lb. Massillon open frame steam hammer, and two smith's hearths, are installed for taking care of special work outside of the regular run of the work, while the availability of the furnaces enable special heat treating to be done on occasion.

The power department consists of a boiler room 65 ft. x 60 ft., containing a battery of 5 Goldie & McCulloch 150 horse-power return tubular boilers for supplying steam to the steam hammers, and general heating purposes. Hydro-Electric power is employed for the various motors and shaft drives throughout,



COLD TRIMMING DEPARTMENT, WHERE DROP FORGINGS ARE TRIMMED TO SIZE IN PUNCH PRESSES.

also shop lighting. As shown in the view of the boiler room, gas firing is installed throughout; owing, however, to the heavy demands on this source of heat in winter time, combined with a steady decrease in available supply, the installation of mechanical coal stokers is now under way.

An Ideal feed water heater and purifier is used, while the feed pump installation consists of one Darling Brothers 10 x 6 x 12 in. duplex piston pump, and a Goldie & McCulloch outside centre-packed plunger pump of similar size.

Turbine Driven Blower

An interesting item of equipment is a blowing unit composed of a General Electric centrifugal air compressor running at 3,400 revs. per min., direct driven by a 75 horse-power Curtis turbine. Forced lubrication at a pressure of 4 lbs. per sq. in., is supplied to the bearings, while the air is delivered to the main blast pipe at a pressure of 11 oz. per sq. in. The exhaust steam from the turbine is utilized for heating the boiler feed water.

All the forge furnaces are of uniform design, so that gas and oil can be utilized to best advantage according to the class of work being heated. The furnaces are placed between the hammers and the walls of the buildings. They are not opposite the hammers, however, but toward either side, with one end toward the hammer so that the operator is not exposed to excessive heat. In this respect, mention should be made of the large proportion of wall area devoted to lighting space. Steel sash of the Trussed Concrete Co. type has been liberally employed, which, in conjunction with the numerous ventilators in sides and roof insures working conditions of maximum comfort and efficiency.

FUTURE SUPPLIES OF IRON ORE

MANY interesting facts regarding the world's supply of iron ore were mentioned by Prof. W. G. Fearnsides in the second Howard lecture before the Royal Society of Arts, May 7. Not only in Britain but throughout the world, there is, at this time, a shortage of ore for making fine acid steel, there is, however, abundance of material for making basic steel.

English iron masters wanting ore for the acid steel process invested money in the Bilbao district in Spain in the eighties, and soon after, Germany became a competitor for the product of these fields. The hematite ore was obtained in open quarries on the slopes of the hills, and the Germans, being second in the field, took the dump heaps that were first turned over. That material was of poor quality, but by bringing in mechanical processes of dealing with it, they obtained a wealth of valuable material.

Nevertheless, the ore fields in the neighbourhood of Bilbao were within measurable distance of exhaustion, and if the 19 million tons of ore per annum which were taken from these fields were taken for another decade there would not be much left. Hitherto the ore had averaged something like 50 per cent. of metal. Whilst, however, the Bilbao fields were getting near exhaustion, the ore fields of Spain generally most certainly were not. Along the coast from Bilbao to the west there were large masses of ore which would become available as soon as transport facilities existed. That district could undoubtedly continue to supply a good deal of non-phosphoric material for a good many years.

French Ore Fields

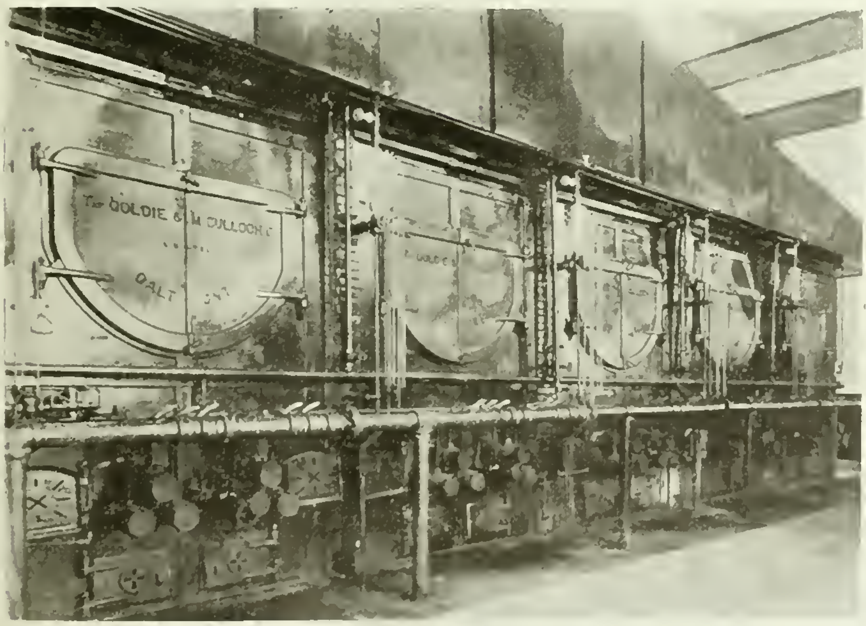
On the borders of France and Germany, around Metz and Verdun, the ores were comparatively near the coal. Briey, Longwy, and Nancy marked the extent of the fields, a distance of 30 miles, and it was there that the great increase of pig iron and steel production, which had been so marked during the present century, had taken place. It had been estimated that, on the German side, there were more than 2,000 million tons of this ore, and on the other side 3,000 million tons. The first thing that the Germans did on the outbreak of war was to advance their armies at all costs to the western side of this ore belt, and since then they had continued to work the mines. But for that source of material the Germans would have found it very hard indeed to maintain their shell supply. The best of the ore was to be found around Briey, where it varied from 6 ft. to 19 ft. in thickness, and contained about 40 per cent. of iron. Briey only became important in the early years of the present century, and whereas in 1900 it only produced 7 per cent. of the total production of the district, in 1913 it produced 70 per cent. The district as a whole accounted, before the war, for nearly 80 per cent. of German iron, and 90 per cent. of the French, and the importance attached to it by the Germans was emphasied inasmuch as all German peace terms insisted that it should all be on the German side.

Sweden and Norway, in addition to sending about a million tons of ore to this country, also sent large quantities to Germany, to which had to be added the output of Swedish pig iron. Most of the ore was obtained from the district to the north-west of Stockholm, and it differed from anything that we had in this country, or that we imported from Spain or North Africa. Much of the material now being made into Swedish iron was raised from the old time workings, the iron ore being picked out magnetically. Even so, the Swedish Government had recognised for the past ten years that there was a shortage, and had prohibited the export of the best material. More important to British, as well as German, ironmasters was the district between Lulea and Narvik. The mass of ore was five miles long and 80 yeards thick. Hitherto we had picked out the less phosphoric material, but the Germans were less particular, and had taken the other, and from it had obtained a production of 5 million tons per annum since the beginning of this century, and they could continue doing so. There were vast resources in the district, and magnificent harbours available, and it seemed exceedingly likely that it would be a valuable source of supply in the future.

American Deposits

Coming to America, Professor Fearnsides said that 80 per cent. of the American ore came from the district of Lake Superior. The bulk of the material contained as much as 50 per cent. of iron. The bulk of the best hematite ore came from the Mesabi Range, where there were between 2,000 and 3,500 million tons waiting to be got. Beyond that there were 70,000 million tons of rather lower grade ore that might at some time be worked.

In Canada it was hardly known how much iron ore would become available. The Lake Superior deposits in the United States continued across the boundary, and were equally productive on the other side. There were also plenty of low



INSTALLATION OF GAS-FIRED BOILERS FOR SUPPLYING STEAM TO THE HAMMERS IN THE FORGE DEPARTMENT.

grade ores available in Canada as well as in Nova Scotia and New Brunswick. Then there were the supplies in Newfoundland, which were worked more under the sea than under land, and produced about 1½ million tons a year, and there was also another great source of supply in Cuba. The latter had been proved to be a quality which was suitable for making pig iron which could be converted direct into alloy steel, as it contained chromium and nickel.

In western France there was a large output which, for want of coal to treat it, had been sent as to two-thirds to Germany and one-third to Great Britain. If Germany could afford to carry that ore to Westphalia, British iron-masters could afford to bring it to England, and larger supplies from that district might be looked for. The ore had been proved to depths as great as 1000 metres.

As to the Colonies, Newfoundland was sending a small quantity to England; there were considerable quantities of ore in Rhodesia, but it was doubtful whether it would pay to bring it to England. There was also plenty in India, as well as in Australia and New Zealand, in each of which countries there was plenty of coal, and in all of them great industries were being set up for the manufacture of steel within their own borders. It was not likely also that South Africa would long be behind.

Reviewing the position, the lecturer said that America, Germany, France and Sweden showed great increase in iron ore output, and all of them were supplying material which required the basic process for its refining. England was comparatively steady, and had not yet adopted that process. The fact was that the supply of hematite ore, and the material suitable for making acid steel, was failing, whilst there was abundance, and no suggestion of a shortage either in Great Britain or elsewhere in the world of the material suitable for the basic process, and it seemed to him that if Britain were to keep pace with the other nations in the race for the world's markets she would have to open out the basic process. It might be said that he who was master of the world's iron was master of the world, and that the question of quality was of more importance than the question of quantity.

CANADA'S 1916 STEEL OUTPUT

THE statistics of production of iron and steel in Canada in 1916 as published by the American Iron and Steel Institute recently show a marked increase over the output of the preceding year. Pig iron production was 1,069,541 gross tons against 825,420 gross tons in 1915. The production of steel ingots and castings last year amounted to 1,286,509 tons against 912,755 tons in 1915. The production of pig iron by grades in 1916 and the four years preceding was as follows, gross tons:

	Basic	Bessemer	Foundry	All Other	Total
1912	489,799	228,742	194,208	129	912,878
1913	558,524	227,662	225,231	3,701	1,015,118
1914	331,456	184,053	174,346	16,117	705,972
1915	660,369	13,714	125,769	25,568	825,420
1916	851,453	12,575	181,748	23,765	1,069,541

The production of steel ingots for last year was 1,255,196 tons and of steel castings 31,313 tons. The production of ingots and castings by processes in the past five years was as follows, gross tons:

	Open-Hearth	Bessemer	Other Kinds	Total
1912	645,062	207,569	400	853,031
1913	768,663	273,391	449	1,042,503
1914	556,910	186,158	284	743,352
1915	884,736	22,521	5,498	912,755
1916	1,245,488	10,968	30,053	1,286,509

The production of finished rolled products in Canada in 1916 was 76,478 tons of iron and 887,332 tons of steel, making a total of 963,810 tons. This compares with the high record of 967,097 tons in 1913. The distribution of finished rolled forms of leading products for the past five years is shown below:

	1912	1913	1914	1915	1916
Rails	423,885	506,709	382,344	209,752	81,497
Structural shapes and wire rods	64,082	68,048	59,050	114,829	174,490
Plates and sheets, nail plate, merchant bars, tie-plate bars, etc.	373,257	392,340	218,125	328,737	707,823
Total, gross tons	861,224	967,097	659,519	653,318	963,810

It will be noticed that rail production last year fell off heavily, due in large part to the extraordinary demand upon steel works for war steel. In the preceding year Canada shipped a considerable quantity of rails into the United States.

The production of iron and steel cut and wire nails in Canada in 1916 amounted to 1,757,000 kegs of 100 lb., as compared with an estimated production in 1915 of 1,636,000 kegs. Cut or wire nails were made last year by nineteen works in five provinces.

The production of finished angle splice bars, tie plates, fish plates and other rail joints and fastenings in Canada by rolling mills and steel works in 1916, all steel, not including spikes, bolts, nuts and similar fastenings, amounted to 6,479 gross tons, as compared with 9,406 tons in 1915, 34,165 tons in 1914, 54,839 tons in 1913 and 52,157 tons in 1912.

The total production of cast-iron gas and water pipe and fittings and cast-iron soil and plumbers' pipe and fittings in Canada in 1916 is estimated at 43,850 net tons of 2,000 lb., as compared with an estimated production in 1915 of 53,700 net tons, a decrease of 9,850 tons.

WATER GAS PRACTICE

By L. E.

THE main problems of carburetted-water gas practice centre around the proper and economical treatment of the oil used for enriching. The tar produced has a lower specific gravity than coal tar, and shows a decided tendency to hold more water in its mass. Occasionally an even worse trouble manifests itself, viz., that a considerable amount of it persists in remaining on top of the water in the tar well and other places. This is caused by incorrect heats and may manifest itself either when the carburetter and the perheater are too cold or too hot.

When the heats are too low a large amount of oil is imperfectly cracked, or not cracked at all, and, passing through the seal-pot, thins the tar and makes a composition that will float. On the other hand, if the heats are too high a large amount of lamp black is made, which will mix with the less amount of tar produced, and the mixed water, tar and lamp black persists in floating.

The oil supplied for use in water gas manufacture is not as a rule quite the same as was delivered in the earlier years of this process of making gas. It very often seems to be a mixture of distillates, for part of which a certain heat is too high, causing stopped pipes and an excess of lamp black, and for the other part the heat is too low, making too much tar, and that of a low specific gravity, and rich in oils somewhat similar to the original oil. Moreover, some American oils reveal a residue that carbonizes on heating and forms deposits on the chequer work in the carburetter, especially troublesome if the air blast enters the vessel rather high up, as a strong flame heats there during the blow, and if much of this carbonaceous deposit collects there it prevents the heats being suitably and regularly maintained.

The oils commonly supplied now often give nearly 50 per cent. more tar than would have been produced under similar conditions some years ago. This indicates the need of higher heat or more heat storage in the chequer work, while a more frequent cleaning of the chequer bricks is also necessary. A little suspected source of tar trouble may be the character of the ash used in the generator, the ash of some coke fuses at the temperature reached during the blow, and is easily removed as clinker. Some of the ash of other cokes does not fuse in this way, and is blown into the carburetber and superheater (in a similar way to the flue dust of ordinary coal gas settings). This ash deposit on the bricks acts as an insulator, and prevents the bricks from being thoroughly heated during the blasting periods. The oil is sprayed onto these insufficiently heated bricks, and the result is the emulsion of tar and water complained of which will not settle in the tar well.

A Foundation for Machine Tool Design and Construction*

By A. L. De Leeuw

The author emphasizes the fact that engineering development has been most rapid in those branches which have had the assistance of mathematics and science. With respect to machine tools, questions are enumerated upon which information is needed in order to follow the line of recent development of the steam engine. These relate particularly to the functions and action of the cutting tool, the action of the cutting lubricant, etc. Experiments already made by the author are outlined and suggested directions of experimentation are indicated.

THE rapidity of progress of the various branches of engineering may be said to be in proportion to the ease with which their principles can be reduced to mathematics. This was perhaps never so clearly shown as in the case of the development of alternating-current apparatus. It may almost be said that the branch of alternating-current engineering was, like Pallas Athene, born full-grown. Here was a case where the science, the mathematics of this branch, was at hand, waiting for somebody to apply it. As a result, alternating-current apparatus has known no period of experimentation, of stumbling, fumbling progress.

Steam Engine Development

Compare this with the slow, hesitating development of the steam engine in its first stages. In that case nothing was known except that steam would exert pressure; but no knowledge existed of the properties of steam, of thermodynamics, nor of the mathematics of engineering materials. The moment that the fundamental facts of thermodynamics were understood, and were reduced to mathematics, the progress of the steam engine became more rapid.

Many instances could be given to show that the opening statement of this paper is true; but the writer believes that the truth of the statement is so well recognized nowadays that further proof may be omitted. There are branches of engineering which are not capable of such rapid development, because their fundamentals are not so much based on science as on art. Though ceramics may be assisted by the engineer, it can never be a true branch of engineering because it depends on art, or skill, and not on science. All that science can do for ceramics is to improve the facilities for applying the art of the workman, for expediting his processes, and for delivering the materials to the artists. The same, though to a lesser degree, may be said of the textile industry.

Development of Machine Shop Methods

There are other branches of engineering which have not had the assistance of science up to the present time, but which might have that assistance if science could dig out the foundations on which these branches of engineering rest. Machine-shop methods have, as a whole, developed so slowly and through so many centuries that we are apt to forget that these methods should, and actually do, rest on fundamental knowledge of materials to be worked, and tools to work with.

Legendary Knowledge

As it is, the knowledge we have is legendary; transmitted from father to son, or from teacher to pupil, by word of mouth. Now and then some article or book has been written describing the methods in use but without giving any fundamentals, and, as a consequence, is soon forgotten or replaced by some more up-to-date or more fashionable knowledge. Considering the fact that by far the greater part of mechanical-engineering work is done in workshops, and that by far the greater work done in these workshops has to do with the cutting of metals, it is really surprising that no positive knowledge exists on this subject. Millions of people have spent a large portion of their lives cutting metals; improvements in tools and methods have been made, and yet, at the present day, we cannot predict along what lines we may look for further progress. Here and there attempts have been made by individuals to reduce to a system the fragmentary knowledge that we have, but without much success. At the best, it may be said that we now have better records of what we are doing than we formerly had, but any little progress we make is due to the cleverness of individuals and not to the existence of a guiding science.

Establishment of Fundamentals

It might be objected here that numerous investigators have collected data and have made comparative tests of machines and tools for cutting metals. The writer needs to point only to the work of Professor Nicolson and The Art of Cutting Metals, by the late Frederick W. Taylor. However, important and meritorious as these attempts are, they do not establish fundamentals, nor were they intended to do so.

We might imagine that the steam engine, without the assistance of mathematics, or the knowledge of its fundamental laws, had stumbled along for a number of centuries, and, by the perseverance and ingenuity of a number of individuals had finally developed into a variety of more or less highly perfected engines, just as machine tools have arrived at that stage. We might then further imagine that some intelligent and inquisitive individual was making comparative tests of these various engines, boilers, etc., and that finally he arrived at a set of data, quite new and of great interest to future designers and users of steam engines and boilers. Such a man would then have done for steam engines and boilers what Professor Nicolson and F. W. Tayor have done for cutting tools and machines. He would not, however, have established a solid, scientific foundation for the design and analysis of steam engines, such as we have at the present time. Such a foundation can only be furnished by the knowledge of the laws of nature underlying the science, and by the ability to apply mathematics to these laws, which makes the laws of nature into laws of mechanics.

Ideal Steam Engine Standard

To go further with the idea: As soon as the laws of thermodynamics were understood and had been reduced to mathematics, it became possible to imagine an ideal steam engine, which is another term for a 100-per-cent.-efficient steam engine, and to show what is the maximum obtainable efficiency in any steam engine. It was therefore possible to express the efficiency of existing or of contemplated steam engines in percentage of the ideal engine. In order words, the ideal steam engine became the standard or unit of measurement. It was no longer possible for any designer or builder to think that he had produced a steam engine of the highest possible efficiency, merely because his steam engine was twice as efficient as some other existing engine.

Mathematical analysis would soon show him that his engine was still very far from the ideal, that is, from the standard, and after building his engine a test would show him how closely he had approached in practice the product he had intended to build. In other words, he could use his theory to check up his practice. The fact that the inefficiency of the engine was known, left the door open for further improvement.

Boiler Design and Construction

Boiler construction, and especially boiler design and furnace design, made rapid progress when engineers began to apply knowledge of physics, chemistry, and of mathematics to the art. Many times analysis showed that the results obtained were very unsatisfactory as compared with the possible results, and that there was no immediate possibility of making improvements, either because here and there was a gap in the engineer's knowledge, or else the proper materials were lacking for the building of a structure such as his mathematical vision had shown him.

*From a paper presented before the American Society of Mechanical Engineers at Cincinnati, Ohio, May, 1917.

The writer needs to refer only to the history of gas engines and, especially, of steam turbines. Though the engineer was not able to accomplish at once the things he wished to do, the problem was formulated and further developments could be grasped and used for the solution of these problems. Disastrous strains in the rotor of a turbine are no longer disastrous; insurmountable difficulties of lubrication are no longer insurmountable; and the steam turbine is with us, though at one time it was merely the vision of the scientist; or, as he is often called by those lacking in vision, the theorist.

Scientific Development of Machine Tools

What are the things we should know about tools and machine tools to enable us to make these important servants of our present day civilization follow the line of development which the steam engine has enjoyed? Is it possible to develop a theory of the ideal machine tool, such as has been developed for the steam engine?

case would it have been less than ½ h.p., assuming a reasonable time element.

If the only function of a machine tool were the removal of metal, we would find that our best machine tool has an efficiency of from 0.12 to 0.22. Even the better of these figures is very low compared with the efficiency of other machines.

If chips could be removed from a piece of work by a straight pull, the ideal machine tool would be one which would remove material with the same amount of power expenditure as that required by the testing machine . While we would not expect to obtain such efficiency in practice, we would certainly aim to reach a much higher efficiency than we are now able to obtain. However, the question is whether material is removed by a straight pull, and this leads to the confession that the writer does not know what the exact nature of the cutting of metal is, and he believes further that he is not alone in his ignorance.

To the writer's knowledge, no experiments have been made which establish the true nature of the cutting of metals with a reasonable certainty. In The Art Cutting Metals and elsewhere, diagrams are shown of the supposed action of a cutting tool, (See Fig. 2.) The writer is inclined to believe that these diagrams represent a very good first guess; but he wishes to point out that this guess is not based on anything better than the inward vision of the authors of these various works. If this guess is correct, then the act of cutting metal is a removal of the chip by tension, and the amount of power consumed for cutting should not be more than that required by the testing machine. If this is so, the total wastage of power in all the machine shops of the world is enormous; and it certainly would be worth while to investigate this matter thoroughly, merely from the standpoint of the conservation of energy. This is not all, however. Every foot-pound of energy wasted in a machine tool means expenditure of power in destroying tools and wearing out machines. It seems to the writer that the problem of this wastage of power, tools and machines is of the greatest importance.

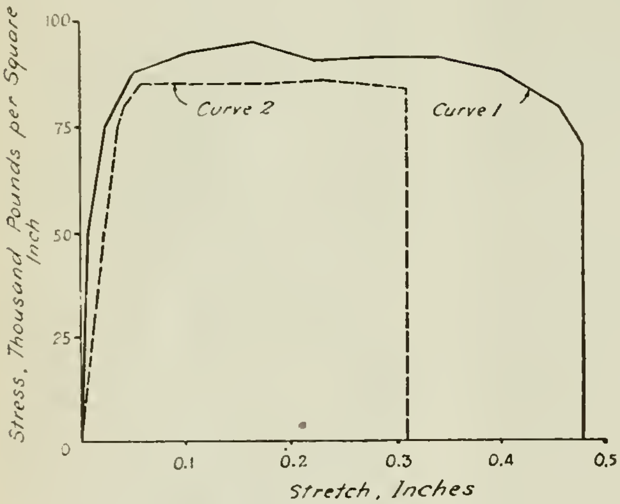


FIG. 1. STRESS DIAGRAMS OF COLD ROLLED STEEL.

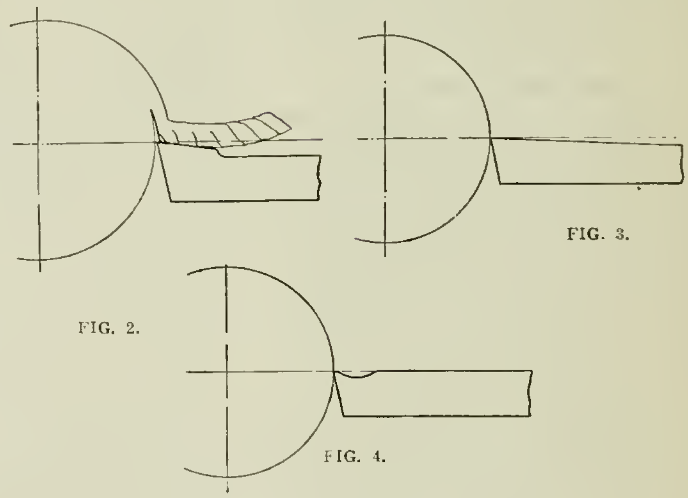

FIG. 2. FIG. 3. FIG. 4.

CUTTING WITH LATHE TOOLS.

Fig. 1 shows two stress diagrams of cold-rolled steel, of which one specimen had a tensile strength of 95,000 lb. and an elongation in 2 in. of 12 per cent., and the other a tensile strength of 85,900 lb. and an elongation in 2 in. of 7.4 per cent. The area of each piece was ½ sq. in. and the length between gripping jaws 2 in. The amount of work done in separating the first piece was 3500 ft. lb. per sq. in. of section, and for the second piece 2000 ft. lb. per sq. in. In parting the pieces, the same result was obtained as if half the piece were removed by means of a cutting tool. Of course, this way of removing metal does not permit of controlling the shape or the finish of the remaining piece; but just the same, a certain amount of metal has been removed as effectively as if it had been done with a cutting tool. If this amount of metal had been removed in one minute by a cutting tool used in one of the present-day machine tools, the amount of power required to do this work would have depended on the quality of the tool and the nature of the machine; but in no

Questions to be answered

Among the questions which should be answered before we can design machine tools in a thoroughly scientific manner are the following:

a—When we turn up a narrow disk by means of a square-nosed turning tool of which the width is greater than the width of the disk, is the action of removing the chip purely a matter of tension? Or, if not, what is it?

b—Does the front end of the tool have any function at all?

c—How far from the edge of the tool is the point where the chip strikes the tool?

d—If the action is purely a matter of pull, and the chip does not strike the top of the tool at the cutting point, but some distance farther back, then is it necessary that the cutting edge of the tool be sharp?

e—What is the nature of the lamination of the chip?

f—How much power is required for the actual removal of the chip, for the friction between chip and tool, and how much for laminating the chip?

g—What would be the best shape for such a turning tool for this particular turning operation?

h—How does the amount of power vary with the various angles of the tool?

i—If the turning operation is not as simple as the one assumed in question (a) if, for instance, there is a side feed, such as in ordinary shaft-turning operations, how is the cutting action modified by this side feed?

j—If the chip is removed by the action of the top of the tool that is, if the front of the tool has no function, then what determines the nature of the finish of a cut?

k—In what relation does the power required for the side feed stand to the power required for the actual removal of the chip?

A great many other questions which could be asked cannot be answered at the present time, and still more questions would naturally present themselves as soon as we had some little elementary knowledge on this subject.

Action of a Cutting Lubricant

As dark a subject as the action of the tool itself is the action of a cutting lubricant. It is a well-known fact that the use of a lubricant and the nature of the lubricant used affect both the finish and the size. A very pertinent question which might be asked, is this: If the chip is separated by tension, that is, if the point where the chip begins to separate from the work is some distance ahead of the point of the cutting tool, how can the cutting lubricant affect either size or nature of finish?

Another equally puzzling question is: If one of the functions of the cutting lubricant is to reduce the friction betwen chip and tool, why should we not use a heavy lubricating oil instead of a light lard oil which has practically no lubricating qualities?

Or again, we might ask this question: If, as facts seem to show, the best results are obtained with a cutting lubricant which has little viscosity and which, therefore, can readily rise between chip and work by capillary action, what is the action of the oil on the separation of the chip, seeing the oil only gets to the point of separation after the chip is separated?

Angles cf Cutt'ng Tools

Even more puzzling than the effect of a cutting lubricant on finish is the effect it seems to have on the size of the work. We do not see at the present time how it is possible for the lubricant to influence the size, yet that it does do this has been observed a great many times.

The writer had occasion to look into this matter when trying to determine the best cutting lubricant for automatic screw machines on small and medium-sized work. The lubricant in use was a mineral oil with 15 per cent. lard oil. A certain job was selected, for which a form tool was used, and 24 screws were made with the regular compound. The screws came true to size within the limit of one-half of one thousandth. The oil was then removed from the machine and machine and tools were cleaned. The cutting compound to be investigated was substituted, and another 24 screws were made. These screws were all larger than those cut with the regular oil. Furthermore, they varied from two and one-half to five thousandths over size. The machine was once more cleaned, and the original oil put back. The screws again came uniform and to size, showing that the cutting of the first 24 screws had not dulled the tool or caused any other disturbing element to enter into the equation.

The fact that the cutting compound caused the screws to be oversize might possibly be explained by a difference in heating or cooling effect of the different lubricants; but how can the difference in size of screws made with the same lubricant be explained when there was no such difference with the use of oil?

Many other questions could be asked which cannot be answered at the present time. This should not prevent us from carefully investigating the true action of cutting metals, and determining the

FIG. 5. PROBABLE RELATION BETWEEN CONTAINED ANGLE OF CUTTING TOOL AND POWER.

fundamental data, if we are interested in this matter in a purely scientific way. However, the engineer should not indulge in scientific investigation unless he feels that the results will be of practical value. To be of value, the results should lie in the direction of saving of power, diminished wastage of tools, and less strain on the machine; or in the direction of increased output, with or without the other advantages. That such advantages may be reached seems very clear to the author, and he wishes to outline some isolated experiments which, though not complete in themselves, point to very interesting possibilities.

Forged spindles of sixty-point carbon steel were roughed by a tool as shown in Fig. 3. As a rule, the tool was able to rough three spindles before a breakdown. In its broken-down condition the tool appeared as shown in Fig. 4. A hollow had been ground out by the chip, but a land of a little more than 1-64 in. in width had been left at the front end, showing that the extreme front of the tool had not been in action. The experiment consisted of carefully measuring the broken-down tools and making new tools of just that shape; in other words, a tool like the old tool, but with a hollow ground in the top of the same shape size, and location as in the old tool.

FIG. 6. FIG. 7.
AUTHOR'S SMALL ANGLE TOOL AND TOOL HOLDER.

This tool is shown in diagram in Fig. 4. The hollow was carefully polished, and a tool thus prepared would rough from 9 to 13 spindles. Examination showed that the hollow in the tool would remain smooth almost to the last, and that a complete breakdown followed very soon after the surface of the hollow began to show scratches. No tests of power consumption were made, but it may be assumed that the power required with the old tool was more than with the new tool, as the chip did not have to bend so sharply and as the work required for hollowing out the tool was omitted.

Another interesting point about this tool was that the actual contained angle between the front of the tool and the front of the hollow was much less than we would have dared to make between the front and top of an ordinary lathe tool, especially if this lathe tool were to be used for roughing. Nevertheless, under the conditions given, this tool with the small front angle stood up better than the original tool with the large angle.

Effect on Size of Work

In "the Art of Cutting Metals," Mr. Taylor stated that his experiments showed no perceptible difference in power consumption for various contained angles of the cutting tool. The writer thought that this conclusion would probably be correct only for the range of cutting angles tried by Mr. Taylor. He imagined that the relation between contained angle and power consumption would probably be a curve of the nature of Fig. 5, and that all the experiments made by Mr. Taylor were within the horizontal part of the curve.

The writer therefore set out to experiment with angles much below the angles mentioned in "The Art of Cutting Metals." Realizing that an ordinary lathe tool would not stand up with much smaller angles than those used in present-day practice, he devised the tool shown in Fig. 6. This tool is a body of revolution, and was held in a rigid block of metal, and directly over the lathe carriage. Fig. 7 shows the arrangement of tool and tool holder used. The tool was used for turning, preparatory to grinding, milling-machine overarms, about $4\frac{1}{2}$ ins. in diameter and 5 ft. long. When the tool gave out, it was turned in the tool holder so as to present a new piece of the edge to the work. In this manner, from 12 to 16 settings could be made with one sharpening of the tool. The sharpening itself was a matter of circular grinding. The tool would make a very smooth cut, and without a steady rest would turn half the length of the bar with a variation in diameter of less than three thousandths. The surface of the work was unusually smooth, and the amount required for grinding was much less than usual. Unfortunately, the lathe on which this work was done was too large and heavy to make accurate power readings for so slight an amount of power consumed, the cut being only 3 16 in. reduction in diameter and the feed 1 16 in. to 3 32 in. The action of the tool was quite peculiar, and did not give one the impression that metal was being cut. Though nothing was learned about the relative efficiency of this tool, the writer thinks it worth while to bring it forward, on account of the possibilities for further investigation to which it points.

This matter of the relation of the contained angle to the power consumption for a given cut had previously led to the introduction of the helical cutter, where the actual angle of the tool is not small, but where the tool is presented to the work in such a manner as to have the effect of a small angle.

Another experiment more or less related to the same question was an attempt to use a rotary lathe tool, such as shown in Fig. 8. The edge of this tool would bear up against the work (Fig. 9), so as to have a very slight difference in speed between the work and the tool, and it was further set in such a way as to make the virtual cutting angle very small. The result was that it became possible to use very high cutting speeds without any apparent effect on the tool. The cutting speed was limited only by the machine. With a reduction of 3/16 in. in diameter and a feed of 12 to the inch, a cutting speed of 650 ft. was used for cast iron as well as for steel. All cutting was done dry. Again no attempt was made to get accurate data as to power consumption, especially as it was realized that the lathe in its present form is not well adapted to this kind of cutting tool. The chips made by this tool were not broken up and were practically solid steel bars. Furthermore, the chips as they came off the lathe were cold enough to be caught in the hand. It is therefore very likely that a test would have shown a remarkably low power consumption.

FIG. 8. EXPERIMENTAL ROTARY LATHE TOOL

Though the foregoing experiments are incomplete in themselves, they do show that there are great possibilities before us, and further, that these possibilities lie away from the present-day shop practice. The writer believes that it would be almost useless to try experiments along a great many lines, and by a great many experimenters without a complete plan of campaign; and that such a plan of campaign should be based on some theory or at least on some hypothesis; and he further believes that no such hypothesis can be developed unless we start in collecting some elementary data.

A few years ago, L. P. Alford, Mem. Am. Soc. M.E., who was then in close touch with the writer on this subject, approached Dr. Stratton, of the Bureau of Standards with a view to having that Bureau take up the first investigation of the process of cutting metal. Dr. Stratton promises the assistance of the Bureau, and at a preliminary meeting a general plan of campaign was discussed. The writer believes that an order was placed for a special dynamometer for measuring the stresses in various directions when planing metal. This proceeding will probably give some valuable data, but, according to his ideas, not of a kind which will make it possible for other experimenters to use them as a basis for their own experiments.

Suggested Lines of Experimentation

The writer believes that interesting results may be obtained by following a line of experimentation such as the following:—An instrument should be built, somewhat along the lines of a microtome, in which a soft material is to be cut by a razor-like blade or tool. This tool should be arranged so that it can present various angles to the work, and tools of various contained angles should be experimented with. The angles presented to the work should vary as to angle of clearance, angle of rake, and angle of shear. A dynamometer, which should be part of the instrument, should register the pull required for the cut. The material to be cut should be standardized, and it is suggested that paraffin may fill all requirements; by selecting a paraffin of standard melting point, we would also get a material of standard hardness. In this manner the relation between cutting angles and power required could be established over a very wide part of the curve. Though the actual figures obtained would not be immediately applicable to metal cutting, it would make it possible to find the controlling law, and, this done, it would then be possible to investigate the cutting of harder materials over a small portion of the curve and compare this portion with the corresponding portion of the curve already obtained. The same instrument could possibly be used for tests on such materials as lead, soft white metal, etc.

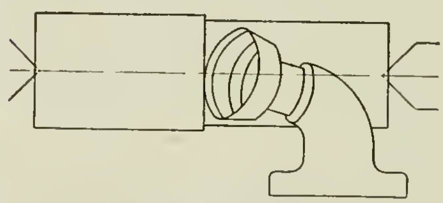

FIG. 9. ROTARY TOOL MACHINING A SHAFT.

Another line of experimentation would be to arrange some machine tool, such as, for instance, a lathe, for running at very low speed, say, 1 in. per hour; mount a steel disc on this lathe, and take a cut at the circumference of this disc. In this manner the cutting action would be of the simplest kind, as the tool to be used could be a square-nosed tool of greater width than the thickness of the disc so that there would be no side cut. A moving picture taken at a high rate of speed could then be reeled off at a low speed, and it would probably be possible in this way to visualize what actually takes place in cutting metal. It would readily show whether cutting is merely the result of tension, or whether shear plays a role, or whether both are responsible. It would probably show whether the chip leaves the work ahead of the tool point, and whether or not the front end of the tool is in contact with the work. It would probably show many other things besides, and might be made the foundation for a number of lines of experimentation.

G.T.R. STRATFORD SHOPS APPRENTICES MAINTAIN THEIR PAST RECORD

THE Stratford G.T.R. apprentices, who have had about forty-five of their number join for overseas service, the most of them now fighting in France doing their bit for the Empire and Canada, and with nearly a similar number working on shells in making munitions to help the boys at the front win their battles, have with these difficulties been able to maintain their high standard by taking first prize at the apprentices' annual examination over the entire Grand Trunk Railway System. For a number of years the other large shops on the system have tried to wrest this honor from the Stratford boys, but have been unable to do so, and not only do the boys themselves feel proud of their achievement, but all employees and citizens in general are glad to know that the boys have again kept up their reputation.

A meeting was held in the assembly hall of the shops on June 1, when Mr. Kelso, master mechanic, congratulated the boys on their success as a class, and also the three individual boys, M. Reynolds, first year; G. Mellors, second year; H. Brayne, fifth year, for having won the highest individual score in their respective years, over the whole system, and H. Brayne for having tied with a Battle Creek boy for fifth year honors over the System. Mr. Kelso also informed the boys that they will get their well-earned excursion, which they are looking forward to. He also called the attention of the apprentices to the untiring efforts on their behalf of former Master Mechanic R. Patterson, to whom must be given the credit of this year's success, as he Mr. Kelso since taking over Mr. Patterson's duties has had so much to learn himself that he had found it beyond his power to give as much time to the interests of the boys as he wished to. Mr. Kelso also reminded the boys of the fact that the other shops throughout the system were not so fortunate as Stratford in having such excellent school facilities to draw from. Other shops have also greater competition in the way of large factories surrounding them, and though full credit is due the apprentices for their success, so much more discredit would be due them if they lost the lead. He also called attention to the fact that the Grand Trunk Railway System is spending a great deal of money for apprentices' welfare, and all they asked in return was faithful attention to duty. Though this year's averages were good, he hoped next year's in both class and shop would be better.

M. A. Humber, the efficient instructor, shares with the boys the distinct honors which have come to the boys of Stratford shops.

The excursion is to Toronto on June 16.

Development of Ocean Service Shipbuilding in Canada--IV.

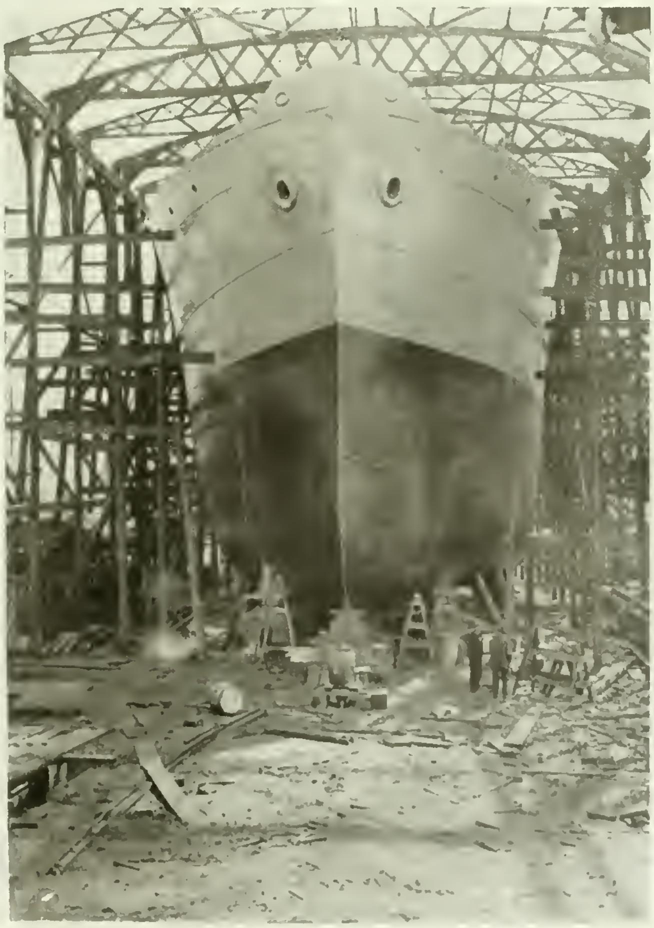
By C. T. R.

In addition to the widespread requisitioning of vessels for transportation purposes by the Allies, the war attendant and normal merchant ship losses and the many months' almost complete cessation of new construction on the part of the latter, the merchant marine of the world has had the misfortune to become to a large extent the target for enemy submarine activity. All nations have suffered in this respect, hence the almost feverish anxiety being displayed by shipping interests to have the losses made good at the earliest possible moment.

S.S. "WAR DOG" LAUNCHED AT NORTH VANCOUVER

WITH the successful launching of the War Dog from the Wallace Shipyards, North Vancouver, B. C., on May 17, another stage towards the completion of the first steel ocean-going ship yet built in British Columbia, was reached. The vessel is 300 feet long between perpendiculars, 45 feet moulded beam and 27 feet moulded depth, and is of the well-decked type designed to carry 4,700 tons deadweight. Work of this class would not, in older districts, attract much attention; but as only a few years ago fire and cedar trees of the largest size grew where the War Dog was built, special interest attaches to what has been accomplished, not only in a local sense, but in its broader and national aspects. Launches and trial trips have, of course, taken place from the Wallace Shipyards before, but only on this occasion was a general holiday proclaimed. A large number of guests were entertained by the management in their characteristic style and as the vessel started down the ways to the waters of Burrard Inlet, she was christened by Miss Barbara Hogg, of Vancouver.

The War Dog has been built to take Lloyd's highest class and has been, during construction, under the supervision of T. G. Mitchell, Lloyd's representative in Vancouver, while H. Darling has acted as owners' representative. The boat was originally laid down for Japanese interests, but has since been taken over by a Liverpool, England shipping firm. The original contract was placed by Messrs. Dingwall, Cotts & Co. The main engines have been built by the Wallace Shipyards in their own shops. They are of the three crank triple expansion type, having cylinders 24 in.-38 in.-62 in. diameter, by 42 in. stroke, and at 70 revolutions per minute will be capable of developing 1,300 indicated horse-power. The propeller is built up, having a cast iron boss and four cast iron blades, its diameter being 15 ft, and its pitch adjustable from 14 ft. 6 in. to 16 ft. 6 in. The main boilers were built by Messrs. J. G. Kincaid & Co., of Greenock, Scotland. They are of the Scotch marine type, 14 ft. 9 in. mean diameter by 11 ft. 0 in. long, and carry 160 pounds working steam pressure. The donkey boiler is also of the marine type, 6 ft. in diameter by 8 ft. 5 in. long, and was built by the Vulcan Iron Works, New Westminster, B.C. The deck winches have all been supplied by the North Shore Iron Works, Ltd., of North Vancouver. The machinery was all ready to install, in fact, all the auxiliaries that could be put abroad previous to launching were in place and piped up. The work of installing the main engines and boilers is being rushed to completion, three shifts of men being employed. The large sheer legs belonging to the builders and capable of lifting 100 tons will take care of the heavy lifts.



BOW VIEW OF "WAR DOG" ON THE WAYS.

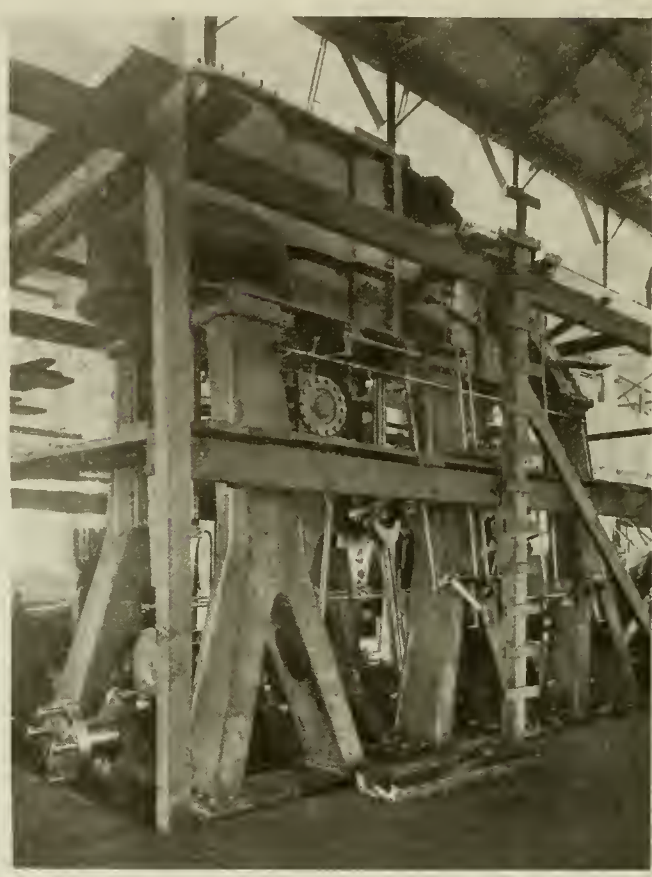
Much credit is due to the staff of the Wallace Shipyards for their accomplishment. Earlier in the war, before the shipping situation was thoroughly understood the firm was engaged in shell production. On completion of their contract, it was evident that more general good would result by getting back to their regular line of work, which they immediately proceeded to do. On the berth vacated by the War Dog, a similar keel will be immediately laid down, work in the drawing office and mold loft for this second ship being now well advanced.

Besides steel constructios, the Wallace yards have several auxiliary power schooners under way. At the time of writing they have had two schooners delivered, one was having the machinery and rigging installed, while three were approaching the launching stage. A large amount of local and deep sea repair work is also carried out at North ancouver, the firm having two marine railways which are more or less constantly employed. Work at No. 1 yard where the steel construction is carried out, is under the charge of R. E. Ellis. H. B. Taylor, the assistant superintendent and chief engineer, has direct charge of the machinery end.

Congratulations Extended

That British Columbia is doing work of great Imperial importance by building ships was the sentiment expressed on the evening of May 13, at the Vancouver Club when Mr. Eadie, on behalf of Dingwall,. Cotts & Co., the firm which placed the order for the War Dog, was host at a dinner to celebrate the successful launching of the vessel the previous afternoon. The Wallace Shipyards, the builders, were represented by Alfred Wallace, R. Elwood Ellis, superintendent; H. Bakewell Taylor, engineer-in-chief, and James D. Baker, naval architect. Others present were, Messrs. Henry Darling, W. E. Hodges, J. M. Bowell, W. H. Hogg, James Hopkins, Ed. E. Sykes, A. H. Sperry, Frank R. Harrison, George Kidd, E. W. Hamber, F. W. Peters, E. H. Beazley, Charles S. Meek, Captain C. H. Nicholson, E. J. Leveson, George V. Holt, Robert J. Borland, P. R. Duncan, H. M. Ellis, J. K. Macrae, W. W. Berkinshaw, B. W. Greer, Knox Walkem, T. W. B. London, and C. F. Boyce.

The evening was devoted to talk of shipping and Mr. Eade expressed the thanks of the community to Mr. Wallace for his courage and enterprise in establishing such an important industry. The ships are afloat and some are en passage, said Mr. Eadie. In submitting the toast, he also paid high tribute to R. Elwood Ellis and Mr. Taylor for their services.



THREE-CYLINDER TRIPLE EXPANSION ENGINES OF THE "WAR DOG" ERECTED IN SHOP.

Various speakers paid compliments to these officials, and a general sentiment was expressed that by building ships British Columbia can be of valuable service to the Empire. In this connection Mr. Eadie submitted a toast to the men of the British merchant service who have kept the commerce of the Empire moving despite the dangers from submarines and mines, in addition to the ordinary perils of the sea. The toast was responded to by Mr. London and Mr. Beazley.

Bankers' views were given by Mr. Hogg and Mr. Holt, while Mr. Knox Walkem spoke on wooden ships. A toast to the popular host was submitted by F. W. Peters. Unfortunately, Captain Crasven, who will command the War Dog, and Chief Engineer Thom, who will have charge below, were unable to be present, but there were many kindly references to them.

ACCIDENT PREVENTION IN SHIPYARDS

THE accident-history of shipbuilding on this continent closely follows that of European countries, where the industry has a high rank among dangerous occupations. A little study of the conditions under which modern shipbuilding is carried on will show why the accident rate is so high, and a little further study will show that many of the accidents are wholly unnecessary.

OCEAN SERVICE STEEL FREIGHTER "WAR DOG" TAKING THE WATER AT NORTH VANCOUVER, B.C.

Many of the operations in the modern shipyard, where steel is the chief structural material, are quite different from those that were in vogue in the good old days of the wooden "wind-jammer"; but the changes that have been made have not greatly altered the nature of the hazards to which the men are exposed, and most of the injuries are still due to falls, or to blows from falling objects. The details of shipbuilding vary from yard to yard, according to the magnitude of the operations, the age of the plant, and the experience and personality of the owner or manager. We believe, however, that the practices and suggestions outlined below are fairly applicable to average yards and conditions, says the Travellers' Standard.

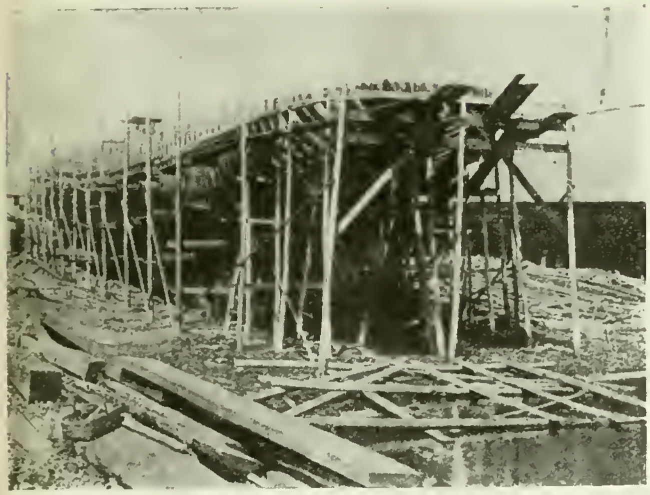


FIG. 1. A THREE-DECK STAGING. THE BOARDS ARE LAID LOOSELY AND NO GUARD RAILS ARE PROVIDED.

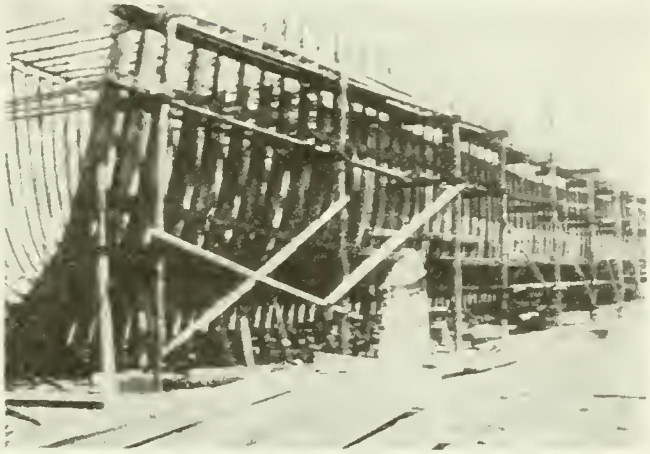

FIG. 2. NEARER VIEW OF A THREE-DECK STAGING.

Staying Feature

Blocks for supporting the keel are first placed on the ground previously prepared, and supports for a scaffold or staging are then erected around the entire space to be occupied by the ship. From an accident-prevention standpoint the staging is one of the most important things in shipbuilding, because a great deal of plate-erecting, riveting, caulking, and painting must be done from it. In the commonest method of staging-construction, two parallel rows of uprights are set in the ground a few feet apart, each upright being provided, from top to bottom, with a series of holes through which bolts may be passed. The bolts support horizontal wooden stringers or cross-pieces, upon which the plank platform of the staging rests. As the work on the ship progresses, the bolts are usually shifted to higher holes and the platforms raised to new levels, though sometimes the old platform is retained and a new one is laid higher up. (In some yards special stagings with metal supports are used, but the safety problem is much the same.)

In many shipyards the men who work on the staging are paid by the piece or area system, and they must raise or lower the staging-platforms themselves. As the shifting of a platform is unremunerative work, it is performed as quickly as possible, and not always with safety in mind. In fact, the accident rate from poor staging became so high, at one time, that a number of shipbuilding companies have placed their staging work in charge of men specially trained to it—nobody else being allowed to move the platform, nor to alter the structure in any other essential way. This plan has worked out very well, largely because these men realize that they will be held responsible for all accidents due to faulty staging.

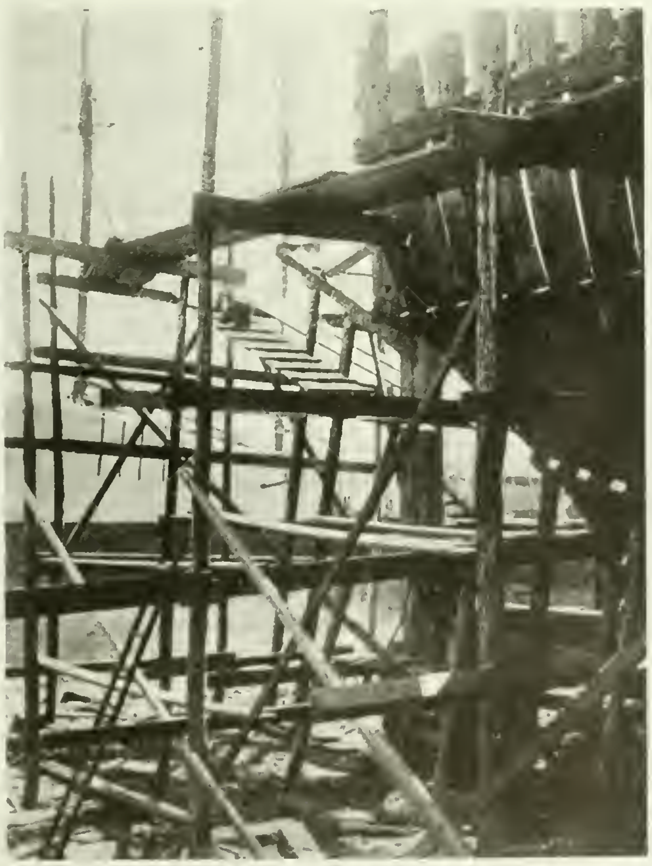

FIG. 3. FOUR DECK STAGING AT STERN OF SHIP. NOTE THE CLEATED RUNWAY LEADING FROM THE THIRD TO THE FOURTH STAGING

Worn or Damaged Plangs and Timbers

One specially marked feature of permitting or compelling the regular workmen to maintain their own staging is the propensity of such men to use timber and planks that are worn out or badly damaged, or defective in some other way, instead of taking the time and trouble to procure sound and suitable material. Planks and timbers that are seriously warped, split, or otherwise badly damaged, should be sawed up or removed from the premises, in order to prevent improper use being made of them. A responsible staging gang, knowing what constitutes a safe working condition and what they have on hand to meet certain requirements, is far less likely to use unsuitable materials.

Men working on a staging often fall from the back of the platform—that is, from the edge that is away from the ship. It is easy to prevent an accident of this kind by erecting a stout railing along the outer row of uprights. A footboard should also be used, and wire-netting between the two is strongly recommended in addition. The railing has been quite generally omitted, mainly because of the time required to install it and remove it. This objection, which is as old as as scaffolding itself, is not a sound one, because the gain from using the railing is out of all proportion to the trouble and expense involved in putting it up. The man who thinks it is not worth while takes this view because he is sure he will not have an accident; but it is a matter of common knowledge that accidents of this kind occur every little while, and it is much better to be safe than to be sorry. In fact, being sorry doesn't do anybody any good.

In some yards plank shelves are put up in place of guard-rails. This is a good plan, because a strong and properly-located shelf affords protection to the men, and it can also be used for the storage of tools, rivets, bolts, paint-cans, brushes, and small materials of all kinds. The shelf should be guarded by a board on each edge, however, to prevent objects resting upon it from falling off.

The platform planks of ship stagings should be laid with special care. To avoid all chance of tipping, they should never be allowed to project, at their ends more than one foot beyond a firm and solid support; and the men who have charge of the laying of the platform should make sure that there are no "traps," or points at which the planks can tip between supports, so that the men can fall through the platform to the ground.

Staging Attachment to Supports

The platform planks of ship stagings are seldom secured to their supports, except at points where considerable work must be done without disturbing the staging. This is because the men desire to avoid the extra labor involved in shifting the platforms, when the planks are fastened down, and also because it is often necessary to move some of the planks nearest the ship, to facilitate the hoisting of plates and other materials into place. The fastening of the planks is far more important in connection with ship scaffolding than it is in connection with the building of an ordinary brick wall, because the jar of the riveting machines and hammers may cause the planks to shift or "creep" until they come into dangerous positions, even though they were correctly placed at the outset. It is well worth while to strap or clamp them to their supports, or to make them secure in some other equally effective way. One method that has been tried with considerable success consists in boring holes through the ends of the planks and through the cross-bars or stringers that support the platform—the cross-bars being made extra wide in this case, to allow for the weakening due to the holes. When a plank is laid down, it is placed so that the hole in one end of it comes directly over a hole in the supporting stringer, and a bolt is slipped through the two, so that the plank cannot shift its position. No cuts are used, and the holes in the platform planks are countersunk, to receive the heads of the bolts. A plank that is secured in this way can be taken up without any trouble.

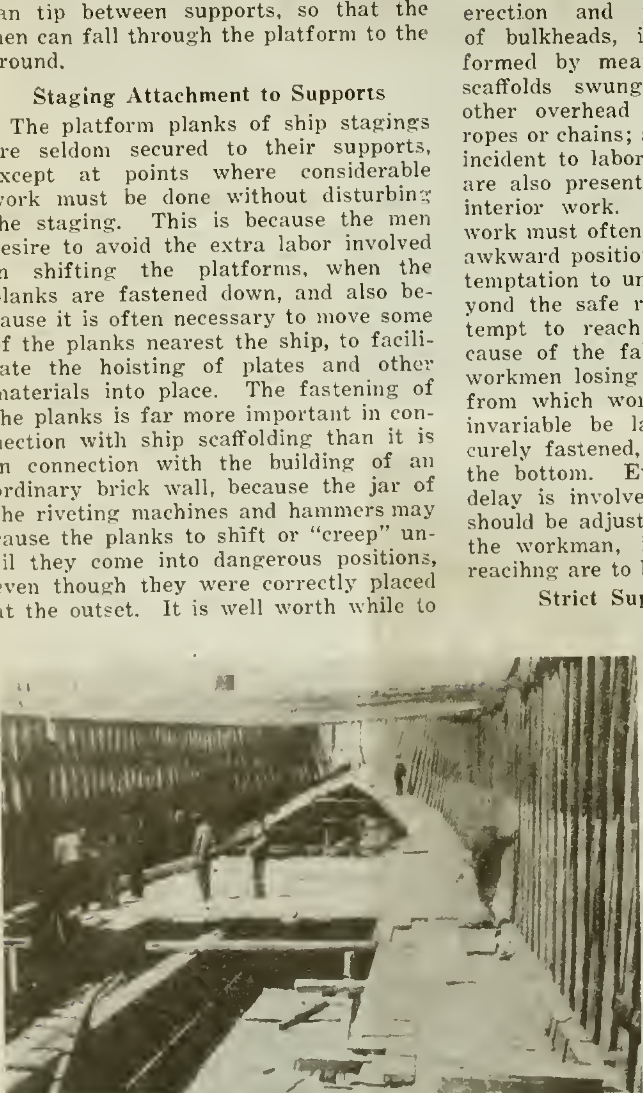

FIG. 4. STAGING FOR THE INTERIOR OF A VESSEL. IN LAYING THE PLANKS, GREAT CARE MUST BE TAKEN TO SUPPORT THE ENDS SO THAT THE PLANKS WILL NOT TIP WHEN STEPPED UPON.

Much of the interior work, such as the erection and plating of bulkheads, is performed by means of ladders, or from scaffolds swung from deck beams or other overhead supports by means of ropes or chains; and many of the hazards incident to labor on the outside staging are also present in connection with the interior work. Moreover, the interior work must often be done from extremely awkward positions, and where there is a temptation to undertake work alittle beyond the safe reaching point. The attempt to reach too far is a common cause of the falling of ladders, and of workmen losing their balance. Ladders from which work is to be done should invariable be lashed, or otherwise securely fastened, both at the top and at the bottom. Even though considerable delay is involved, stagings and ladders should be adjusted to the convenience of the workman, if accidents from overreacihng are to be avoided.

Strict Supervision Required

In view of the vast amount of work that must be done from shipyard stagings, strict supervision should be exercised over the construction and maintenance of all structures of this kind. A busy yard can ill afford to dispense with the services of a capable staging supervisor and his gang of workmen. It is certain, for example, that a competent supervisor would not permit a doubledecked staging to be used, without adequate overhead protection to the men on the lower level; yet scaffolds of this kind, without any protection whatever, are very commonly seen in shipyards.

In building a ship there is a certain point at which the accident rate is likely to reach a "peak," and experience shows that this occurs when the framework or ribs of the vessel are being placed. The ship is then a mere skeleton, and the men have to perform arduous work with very insecure footing. During stormy weather they are likely to lose their balance from gusts of wind, or beams or plates that are being swung into position are likely to be suddenly swerved by the wind, at great peril to the men. There does not seem to be any way to provide satisfactory safeguards in connection with this part of the work. Only the most skilful and careful men should be employed at it, and they should be set at other tasks whenever the weather conditions add materially to the hazard.

FIG. 5. RIVETERS WORKING FROM A SUSPENDED STAGING. THE RIVET HEATING FORGE AT THE LEFT IS TOO FAR FROM THE RIVETERS FOR SAFETY OR EFFICIENCY.

Another hard problem to deal with is the elimination of cuts and bruises and other minor injuries, which are very numerous in the aggregate. Cuts due to handling steel plates with sharp or ragged edges, and finger bruises and lacerations from hammer blows, or from punching or shearing machines, are especially common. It cannot be said that the employment of none but skilled labor constitutes a remedy, for in the main the work that produces these injuries is already in the hands of skilled workmen. The only solution appears to be, to stimulate the men in every way possible, to exercise personal caution.

Hoisting Equipment Risks

Derricks, gantry cranes, and overhead railways are employed to hoist girders, machinery, and other heavy parts, and to transport them to various sections of the ship. During certain stages of shipbuilding, specially skilful handling of the crane and derrick loads is necessary if serious accidents are to be avoided. The men on the skeleton of the ship have a precarious footing at best, so that poor judgment, or a misunderstanding of signals, when lowering or swinging a load, may either cause a workman to be thrown down from his position, or cause him to miss his footing in his quick endeavor to escape. Here, again, is an illustration of the need of providing a competent safety man to actively supervise all operations of a dangerous character.

Unprotected Openings

So far, we have dwelt mainly on accidents due to falls from staging, ladders, and other elevated structures. One other source of falls must also be prominently mentioned. It would be hard to name an industry in which there are more opportunities than shipbuilding affords, for falling into unprotected openings. In the modern vessel with several decks there are many openings for ventilators, bunker hatches, and other permanent uses, in addition to those that are left for temporary building purposes. Unless these various openings are covered over whenever they are not actually in use, workmen and others who may have occasion to go near them are in danger. Stout wooden covers, with the edges on the upper side beveled, are excellent safeguards, and when they must be left off to admit light and air, strong wire-mesh guards may be used instead of solid wooden ones. As workmen are prone to remove covers of this kind, and leave them off, it should be the duty of some one specified man to see that a sufficient number of proper covers are provided, and that they are kept in plance.

The influence of poor illumination on the accident rate in shipbuilding has been very marked in the past, but there is evidence that lighting conditions are being rapidly improved. Formerly a ship under construction, having no self-contained lighting-plant, usually depended on gasoline torches or oil lamps; and this condition still exists in many sailing vessels and in some steamships. Explosions and fires, with resultant burns, were frequent occurrences. In addition, parts of the ship that were not much frequented were left in total darkness, while other parts were not lighted well enough to permit a maximum of efficiency and safety in the work. Of late years, the extension of lines for the transmission of electrical energy, and the installation of power-houses at the shipyards themselves, have made available a very flexible source of power and light. It is a simple matter to string wires to any part of the ship and to use the particular size and type of lighting-unit best suited for the space to be illuminated. Particular attention should be given to the lighting of the approaches to the ship, where large-sized lighting-units, suspended well above the ground, are desirable.

FIG. 6. WELL CONSTRUCTED MAIN APPROACH, WHICH IS A PERMANENT STRUCTURE, GIVING DIRECT ACCESS TO THE UPPER DECK OF A SHIP ON THE STOCKS.

Passing Hot Rivets

Each year shows a number of serious and fatal accidents to boys of from fifteen to eighteen years of age. While serving their apprenticeships the boys are at first employed as rivet-heaters, rivet-catchers, and markers, and in performing work of this nature they are often stationed at high elevations and in dangerous and exposed parts of the ship. The boy who heats the rivets throws them to another at some distance, who catches them in a keg or bucket and quickly places them in the holes for the riveter to drive. Speed is essential in order that the rivets may be as hot as possible when they reach the holes. It is evident that the ability of the rivet-heater to throw the rivet accurately has an important bearing on the safety of the rivet-catcher as well as upon that of other employees at work below. If the rivet-heater's aim is poor, the catcher must either reach out at the risk of losing his balance, or else allow the rivet to pass on with the chance of striking someone below. None except mature men should be assigned to this work; and those at work directly beneath the rivet-catcher should be protected by hanging a substantial, close-meshed wire-netting under the working area, and moving this netting as the work progresses.

Accidents From Falling Objects

Accidents from falling objects are of frequent occurrence in shipbuilding. Planks, bolts, hammers, wrenches, driftpins, and various other tools and materials, are often displaced or accidentally dropped by workmen, and the vibration resulting from the incessant hammering and riveting also contributes to the general downfall, to the constant peril of workmen stationed below. Accidents of this nature can be greatly reduced by strapping or bolting the platform planks of the staging, as already recommended, and by providing all staging platforms and all shelves and other storage places with effective toe-boards or side-boards. Substantial overhead shields should be erected for the protection of all men who are stationed where they might be injured by the fall of objects from work-places at a higher level, and like protection should be erected over all passageways or gangways where a similar hazard exists. The spaces between the staging platforms and the hull of the ship should also be bridged over, as far as practicable, with wire-mesh guards supported on pins thrust through holes in the bearer-bars of the staging, or in some other effective way. These can be made in sections, and used over and over.

Approach Gangways and Runways

The main gangways or runways, leading from the ground to the interior of the ship or to the staging platforms, should be well constructed and of ample proportions. They should be properly railed, and provided with suitable landings at the top. When ever there is any likelihood of material falling from them, they should also have toe-boards at both edges. A ramp or runway having a gradual rise, and provided with substantial hand-rails on each side and with cleats to prevent slipping, increases the efficiency and the safety of the men. It seems hardly necessary to point out the importance of promptly removing ice and snow from all runways and platforms, and from all parts of the ship. Further protection should be provided by the liberal application of sand or ashes.

When the staging is dismantled, the various parts of it should be lowered to the ground by means of ropes, instead of being thrown down. If the material is thrown down there is always the chance of some one inadvertently getting in the way of a falling plank, or some one at a supposedly safe distance being hit by pieces that take unusual rebounds. With careful lowering, the timber is also far less likely to be broken or otherwise damaged.

Some shipyards do overhauling and repairing, as well as new work; and although the hazards in yards of this kind are similar, in the main, to those that exist in yards that do construction work only, there may be certain minor differences. A ship is not earning dividends while she is in the repair dock, and for that reason her owners usually insist that she be placed in commission again at the earliest date possible. This means that the repair men must plan in every way to save time, and a limitation of this kind often introduces new dangers.

Paint Work Hazards

For example, painting the interior of the ship with standard, oil-mixed paints necessitates considerable delay for drying, both between coats and after the finish has been applied; and in order to eliminate this delay it is customary to use quick-drying paints, containing highly inflammable substances, such as benzine, benzol, or alcohol. Paints of this nature hasten the work, without doubt; but the use of them is attended by the risk of explosions and fires, and they may also produce injurious effects on the workmen. When paints containing volatile constituents that are inflammable or toxic are used in confined places no open lights should be permitted, and smoking or the use of matches for any purpose whatever should never be allowed, on pain of immediate dismissal. The men should also have frequent periods of rest in the open air, and foremen should inspect all confined workplaces at least once every half hour, while the work is going on.

Good ventilation is highly important wherever paints such as we have described are being used, and if the quarters in which the men have to work cannot be ventilated easily and effectively by natural draft or by fans, a plentiful supply of fresh air should be introduced by means of a centrifugal pump and one or more lines of large canvas hose. The air should be delivered, in such cases, at the innermost part of the space, so that the objectionable vapors will be removed as thoroughly as possible. If the work is being done in a pit-like or well-like space, each workman should also wear a belt with a stout life-line running up to the entrance to the workplace, and two men should be stationed above, to draw the workman up to safety in case they become overpowered, or show signs of drowsiness or of unnatural exhilaration. In some cases it will also be advisable to provide the workmen with special respirators, supplied with fresh air by a pump.

First Aid Installation

In view of the large number of minor injuries about a shipbuilding plant, it is highly important to provide a first-aid room, or a hospital. Bruises, slivers, and cuts are not necessarily dangerous if they receive proper attention at once, but the average man will seldom quit work in order to attend to a slight injury, unless he can be treated immediately, so that he can return to his work without much delay. Even though he knows of hundreds of cases of blood poisoning due to the neglect of seemingly insignificant wounds, he will "take a chance" rather than go to his home, or to the office of his family physician, for the treatment of a minor injury; but he can have no logical objection to receiving proper treatment by a competent person at the yard. The facilities at hand should be sufficient to render first-aid in the case of serious injuries also, because proper treatment of this kind has a large influence on the ultimate recovery of a badly-injured man. It is important, however, to see that all first-aid work is done by a fully qualified person. Otherwise a great deal of harm may result.

In the shipbuilding industry there are quite a number of cases of lead poisoning every year. The exposure is usually incurred while sandpapering painted surfaces or removing old lead waste (sometimes in confined spaces such as tanks, or between double bottoms or in bilges), or from breathing the fumes that are produced when red-hot rivets are placed in holes lined with red lead. Exhaust ventilating systems and a sparing use of lead paints tend to reduce this hazard.

Educational safety work is specially important in the shipbuilding industry which is admittedly a dangerous one. Moreover, the operations that must be performed are of such a nature that it is hard to provide mechanical safeguards that will afford a protection comparable with that which may be had in many other similarly hazardous employments. Hence it is doubly important to study and promote safe methods of doing the work, and to instil the principle of personal caution into every employee about the yard. If the men can be brought to look at the safety question from the right point of view, and good "team work" can be secured, the accident rate will certainly fall off to a remarkable extent.

HELIGOLAND

THE little island of Heligoland rises abrupely out of the North Sea some thirty-four miles northwest of Cuxhaven. The Germans, since the cession of the island to Germany by the United Kingdom in 1892, have spent vast sums of money on it, in the effort to make it an effective naval base. They have built a sea wall of steel, granite, and concrete, twenty-five feet high, all around it; they have constructed a harbor for submarines at great expense; they have honeycombed the rock of its mighty cliffs, two hundred feet high, with galleries; in fact, they have done everything that could be done to transform the island into a "bristling fortress." What they have done, however, is as nothing as compared with what they have been credited with doing, by those who, with a sorry knowledge of the facts, insist on regarding Heligoland as little less than the key to the naval and military strength of Germany. Germany has, of course, done much to the island since the outbreak of the war, but how much is a question which could never, probably, be answered to everybody's satisfaction, because nobody, except the German authorities, knows.

The Heligoland of the days before the war was open enough for anybody to see. Many visitors in the summer months of each year were wont to seek out its shelving beach of white sand, and indulge in sea bathing, in climbing the high red cliffs and in walking about on the green Oberland. And the first thing that struck the new visitor must surely have been the smallness of the place, a little triangular piece of land just a mile long and barely a third of a mile across, only one-fifth of a square mile in all. Centuries ago, Heligoland was at least five times its present size, and a place of no small importance. Like so many islands, it had a peculiar attraction for the people of the surrounding mainlands. They stood in awe of it, and mythology early claimed it for its own. Here the Forseti, the god of justice, had a temple, and had also, according to another tradition, the goddess Hetha, a special object of veneration among the Angles of the mainland. Later on it was the realm of the pagan king. Radbod, and it was hither that St. Willibrod came, in the Seventh Century, preaching Christianity. But all the while the ownership of Heligoland was in dispute. Sea rover fought sea rover for possession of the island, until at last it became a fief of the dukes of Schleswig-Holstein. Even then, however, it had little rest, for when ever the dukes of Schleswig-Holstein found themselves in need of ready money they had a way of hypothecating Heligoland for loans advanced by the free city of Hamburg. Ceded to England in 1814, the island was, as already noted, transferred to Germany in 1892, and the Heligolanders did not welcome the change. They are not, as one writer clearly points out, Germans in any modern sense; neither have they, by race nor language, any affinity with the Dutch Frieslander. They are, indeed, generally supposed to be survivals of the Saxons who remained behind when Hengist and Horsa and his followers set sail for England. But whoever they are, they are no longer, if one may be forgiven the paradox, for according to all reports, the civil population of the island was removed within forty-eight hours of the outbreak of the war.

LACHINE CANAL TRAFFIC DURING MAY

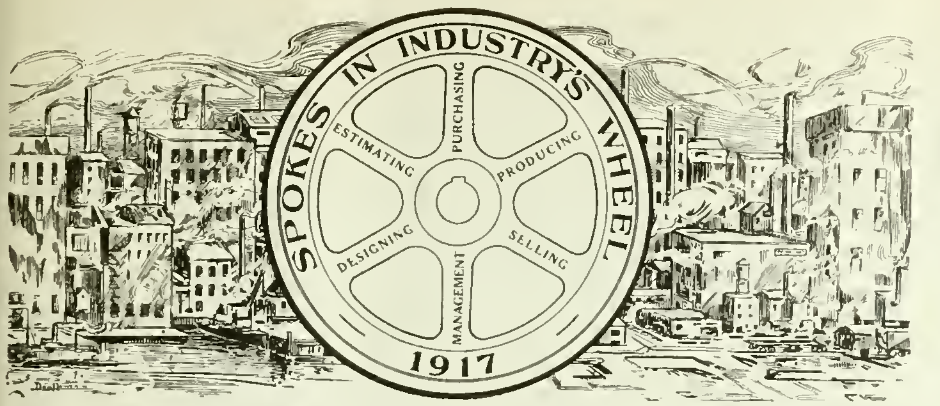
THE shipping through the Lachine Canal in the month of May, shows marked decreases in almost every feature as compared with the corresponding month of last year. Grain shows a decrease of 1,358,161 bushels, eggs of 2,040 cases — almost fifty per cent., cheese of 5,801 boxes, and coal of 27,330 tons. Butter alone shows an increase. The total tonnage operated was 452,407 as compared with 523,999 last year, and the number of trips through the canal decreased from 968 to 936.

The total for each of the different grains shipped through the canal during the month in bushels is as follows:—

	1916.	1917.
Wheat	1,865,468	1,256,295
Corn	185,340	178,071
Oats	1,298,615	1,026,500
Barley	487,206	197,200
Rye	132,000	......
Flaxseed	99,598	52,000
Totals	4,068,227	2,710,066

The decrease in produce was equally marked with the exception of butter, which increased from 308 packages to 431. Eggs decreased from 4,186 to 2,146, and cheese from 18,649 to 12,848. Coal also showed a decrease, the total for May, 1917, being 218,512 tons, as compared with 245,842 for May, 1916.

The trips through the canal during the past month were 936, a decrease of 32, as compared with the same month of last year; the tonnage operated was 452,407, a decrease of 71,592 tons, and the cargo tonnage was 377,003, a decrease of 29,165 tons. The passengers through the canal, however, increased from 1,436 to 1,826. The number of light trips through the canal was 401 in 1916 and 383 in 1917.



The constitution of industrial enterprise is largely departmental—"spokes in a wheel." This series of articles has for its object the featuring in a racy, interesting and instructive fashion, the training, experience and achievement of those who to-day are transmitting, effectively, energy in their capacity as "spokes in the wheels" of our metal-working establishments.

WALTER LAMBERT

EVENTS of the last few months have emphasized in no uncertain manner the extent to which Britain is dependent on her mercantile marine in the matter of maintaining a full larder in the "Tight Little Island." Present and prospective developments in the art of shipbuilding loom up with impending greatness, and the vital necessity of the present crisis imparts thereby a more than usual interest to the personality of the men behind the ships.

Walter Lambert, A.M.I.N.A. is a representative specimen of that type of Britisher whose availability at the psychological moment has, on frequent occasion in times gone past, served to maintain the supremacy of the British Empire, be the location north, south, east or west. A brief resume of our "Spoke's" career will serve to convince the reader that, no matter where the "Outpost of Empire," when necessity calls, a Son of Albion will be ready, possessed of the requisite scientific and practical training to "carry on."

Of English birth and parentage—he was born in Warwick, England, Jan. 31, 1884—Mr. Lambert would seem to have inherited those characteristics which prompt one to record that in this case a naval architect was born as well as made. Son of a father—an artist—and grandson of the owner of the first screw-propelled steamship on the river Tyne, Walter Lambert may well have felt an inner impulse in adopting his present vocation.

After receiving his boyhood education in government High School, London, he attended the West Ham Technical Institute, taking special engineering subjects, preparatory to the adoption of his present profession. In this connection, it should be remarked that he earned the 1st class certificate for the advanced Stage of Naval Architecture in accordance with the South Kensington regulations.

At the age of fifteen he commenced his apprenticeship in the drafting-room of the Thames Iron Works, London, well known in the past as builders of battleships and among his experiences during the three years he spent here was that of attending the launch of the British battleship H.M.S. Albion by the present Queen, then Duchess of York. On this occasion the usually enjoyable and con-

WALTER LAMBERT

gratulatory features of the event were utterly destroyed by the tragic drowning of thirty visitors due to a section of the staging being washed down by the backwash from the ship as it entered the water. The remaining two years of his apprenticeship were served with the Londonderry Shipbuilding & Engineering Co., at Londonderry in the North of Ireland, the miscellaneous mercantile types of vessels turned out at this yard proving a valuable complement to the more dignified and stereotyped war vessel work previously engaged in.

But, of making many ships, like making many books, there is no end and, applying the prophet's dictum to his own work, our "Spoke," on the termination of his apprenticeship, proceeded afield to satisfy his broadening vision and acquire that knowledge which cometh from experience. After two years spent as a junior draftsman with Armstrong Whitworth & Co., Newcastle-on-Tyne on construction of light cruisers and fast scouts for the British and foreign navies, Mr. Lambert joined the staff of John I. Thornycroft & Co., at London and later at Southampton and for eight years was engaged on the design of torpedo boats, destroyers, submarines, motor boats, shallow draft vessels etc., the successful specialisation in which has earned such a world wide reputation for that firm. Mr. Lambert became acting chief of design and foreign construction drafting-room before severing his connection with them to take up the management of the Canadian business of John Reid & Co., Naval Architects & Marine Engineers, Montreal and New York. Mr. Lambert recently completed four years in their service which he terminated in order to commence business on his own account. During his association with Messrs. Reid there was carried out the design and constructional supervision of two lake steamers, two dredges, one train ferry, one self-propelling grain elevator, half a dozen tugs and a similar number of hopper scows all of steel construction; four wooden steamers were also completed.

While nonpartisan in political and municipal affairs, Mr. Lambert has decided views on the present state of world affairs. He is a member of the 5th Royal Highlanders of Canada, and even as this is written, official recognition of the value of his ability is afforded in the announcement of his appointment as Superintendent of Construction to the Director of Steel Shipbuilding, Imperial Munitions Board.

In addition to the professional accomplishments indicated by the foregoing Mr. Lambert holds the position of surveyor to Bureau Veritas and is also Canadian representative of Fleming & Ferguson, Dredge Engineers of Paisley, Scotland. His social activities include membership:—Institute of Naval Architects, Great Britain; Canadian Fisheries Association, and Hudson Yacht Club. He is married and resides in Montreal during winter, while summer finds him either at Hudson, P.Q., or Lake of Two Mountains, where his favorite pastime of boat-sailing and water sports generally can be fully gratified.

As would be expected, our "Spoke" has positive opinions on all questions pertaining to Canadian shipbuilding, and has great faith in the future of the industry, provided it receives judicious encouragement from the Government along with proper financial backing from those engaged therein. The future personnel of the industry must also receive wise training as well as encouragement, and, in this matter of training the future generation, Mr. Lambert believes that a decision ought to be made for a boy before he is fully competent or sufficiently experienced to form his own opinion. "After a boy is 12 years old his education should be suited to his intended line of business, especially if engineering professions are concerned because this age is the most valuable for the acquiring of new knowledge. I believe it would pay shipbuilding firms to take the greatest possible interest in their apprentices, allocating part of their time to purely scholastic and technical instruction. The example of Canadian Vickers is well worth emulating and enlarging upon in this connection,—they hold classes every winter, taking up naval architecture as a science under the direction of their naval architect.

The study of all technical journals bearing upon their business is of greatest importance to mechanics, young and old. Personally, I get through a dozen per month and though at times they pile up because of pressure of work, I regard the close study of modern developments made available by these journals as most essential to successful work."

CANADA'S SHIPBUILDING PROSPERITY

IN the House of Commons, Ottawa, on June 1, the estimates for the Department of Marine and Fisheries were up for discussion, a circumstance which gave the Hon. Wm. Pugsley opportunity to bring forward his favorite theme of encouragement of wood shipbuilding construction in Canada and the Hon. J. B. Hazen, Minister of Marine and Fisheries to outline quite fully in reply what was at present being done both as regards wood and steel construction. The debate lasted for a whole afternoon.

The main point of Mr. Pugsley's contention was that the Government instead of spending money on highways should devote its energies toward aiding the building of smaller wooden vessels in Canada so as to help the coastal and inland water borne traffic which he said was suffering greatly by reason of lack of shipbuilding.

Hon. Mr. Hazen replied that the granting of contracts for 2,500 ton wooden ships only was a matter entirely within the control of the Imperial Munitions Board, which was acting under explicit instructions from the British shipping Controller. The Minister explained that he had brought the matter to the attention of the shipping controller and had suggested that smaller vessels might be ordered. He had received no answer to that communication yet.

In reference to demand for Government ship construction, Mr. Hazen pointed out that in the Maritime Provinces 48 wooden vessels were under construction. It was evident from the activity in the shipbuilding industry and from the fact that ships were sold at a good profit that there was no need for bonusing the construction of wooden ships in Canada at the present time.

"The question of building ships by the Government to be run in connection with Canadian railways is an important one and one to which consideration is being given," said Mr. Hazen, pointing out the necessity for moving carefully in view of the large expenditure that would be necessary and the difficulty of financing such an undertaking at the present time. So long as the profits were sufficient to encourage private enterprise the Government would not be justified in entering into competition.

E. M. MacDonald, Pictou, considered the Minister's statement unsatisfactory. Apparently the Government was content to rest upon what the British authorities were doing, instead of encouraging the building of ships for the Canadian coastal trade. The ships being built for Britain, he pointed out, would not supply the need for Canadian coastal vessels.

Hon. Mr. Pugsley insisted that the building of wooden ships was of primary importance to Canada and declared it was a mistake in view of this for the Government to propose spending $10,000,000 on highways. He read a letter from W. L. Gear, director of steel shipbuilding, stating that the Munitions Board had been authorized to build a certain number of wooden ships of approximately 2,500 tons each, 250 feet long and 40 feet beam. With regard to construction in eastern Canada, the essential point would be to satisfy the Board that suitable lumber could be secured, as they could not rely on getting this lumber from British Columbia, owing to freights and its use in shipbuilding there.

In view of this, Hon. Mr. Pugsley argued that as the Government controlled a Transcontinental railway they should utilize it for bringing suitable lumber from Prince Rupert to points in the east where ships of 500 tons and upward could be built.

Hon. Charles Marcil said there was a time when the mother province of Quebec shared with the glories of the Maritime Provinces in shipbuilding. All that had been said regarding conditions in the Maritime Provinces applied ten times more forcible to the St. Lawrence with its immense traffic and the greatest port of Canada. He painted a gloomy picture of shipbuilding in Canada, declaring that there was an increasing shortage of tonnage everywhere, both on the ocean routes and on the inland waters. He, therefore, strongly argued that no time be lost by the Government in aiding shipbuilding so as to assist the carrying trade of the St. Lawerence and the Great Lakes.

Hon. Mr. Hazen replied that he hoped Mr. Marcil was generally better informed than he was on the question of shipbuilding. He produced figures showing that six large steamers were being built at the Vickers' Works, at Montreal, of seven thousand tons each, another vessel of 2,300 tons and several other vessels of lesser tonnage, while today 2,000 men were busily employed there. He also showed that a large amount of shipbuilding was being done by the Davies' plant at Levis, by private companies at Sorel, and that a company on the Isle of Orleans was building four wooden ships running from 1,500 to 2,000 tons each. The Minister said he had been informed by Mr. Norcross that a large quantity of British Columbia timber was being used in these vessels, a total of nearly a dozen being built at various points on the St. Lawrence.

Hon. Mr. Hazen then instanced a number of points in the Maritime Provinces where vessels were being built, while at Port Arthur five of 3,400 tons were being built, several large vessels at Collingwood, eight large steamers at the Polson Iron Works at Toronto, and a number of others at various points on the Great Lakes and other parts of Canada. The net result, he said, was to show that far from Hon. Mr. Marcil's contention being correct there was a very great activity in shipbuilding in Canada.

As to wooden vessels, Hon. Mr. Hazen said the British Government had issued an order excluding sailing vessels from the war zone, owing to their inability to escape from submarines, but this might not apply to vessels using auxiliary power.

U. S. S. CORPORATION TO BUILD CANAL BARGES

FOR the present the United States Steel Corporation is considering building nothing but steel boats, 12 feet depth, that will go through the barge canal. It was for a site for a plant for such construction that the corporation purchased through Joseph P. Day from the Newark Factory Sites, Inc., the half mile frontage on the Hackensack River adjoining the Newark branch of the Jersey Central Railroad. The tract embraces about sixty-two acres, running back 1,400 feet to Hackenseck avenue. Adjoining this property is another tract of eighty-eight acres, which E. H. Gary is considering purchasing, and if later on the Steel Corporation decides to go into the business of building larger vessels this property will be taken over and improved. It is understood that Chairman Gary, James A. Farrell, president of the Steel Corporation, and August Ziesing, president of the American Bridge Co., picked out the Hackensack River site after having made an exhaustive study as to railroad facilities, labor market, and depth of channel of all the tidewater property around New York. An important factor was the width of the river at the point chosen. The property is right in the centre of the Newark meadows and was partly filled when the Hackensack river was deepened recently.

The tract is midway between Jersey City and Newark and fronts about 1,200 feet on the Lincoln Highway. On one side is land recently taken by the Government for a wooden ship plant, and almost adjoining is the site of the Ford Motor Company's new $10,000,000 plant. The labor required to operate these new industries will roll up into the tens of thousands.

PRODUCTION METHODS AND DEVICES

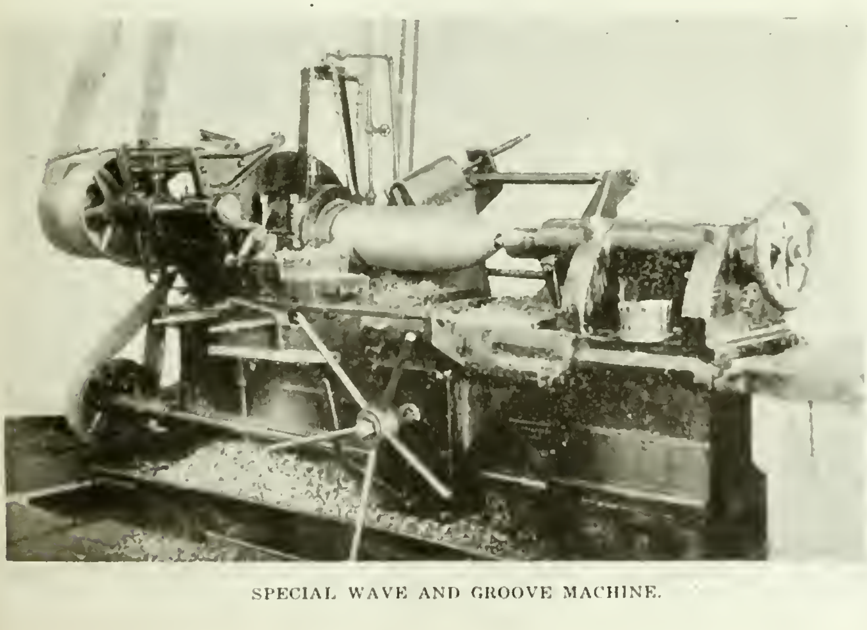
SPECIAL WAVE AND GROOVE MACHINE

By J. H. R.

ONE of the details in connection with the manufacture of shells has called for considerable ingenuity on the part of plant executives, and that has resulted in the design and construction of numerous devices for its accomplishment, has been the operation of waving the ribs and undercutting the sides of the groove into which the copper rifling band is pressed. Owing to the firing duties that are imposed upon this important portion of the shell, strict adherence to dimensions and specifications are essential for the accurate fulfilment of the desired conditions. The two principal characteristics of the copper band groove are the staggered position of the ribs and the dove-tailed sides of the groove; the former to prevent the band turning and the latter to retain it in position when the shell is being discharged from the gun. The failure of either of the conditions will destroy the predetermined flight of the projectile, and may often result in destruction where not intended.

With a certain objective in view it may seem surprising that the actual accomplishment of the machining operation should be obtained in such a variety of ways, but when it is realized that many of these attachments were designed and constructed without outside aid, being based on previous individual experience and available plant resources, it is not remarkable to see so many different details in the operating mechanism of these fixtures. The cut herewith illustrates a special machine designed and constructed by the Ingersoll-Rand Co. of Sherbrooke, for machining the copper band groove on 8 inch shell. With the groove roughed out at a previous operation, the shell is held firmly on a special expanding arbor, the nose end being supported by the tail center. The lathe is provided with two saddles; the forward one, which carries the front and rear tool slides being permanently set in the desired position, the inward motion of the cutting tools being obtained by the cam bars secured to the traverse saddle. The undercutting tools are supported in slides at the rear of the fixed saddle; these slides being set at the desired angle for undercutting, and located at as ufficient distance apart to prevent the slide from interfering when operating.

The special feature of this machine is however, the arrangement provided to oscillate the waving tool slide in a parallel direction to that of the lathe sindle or shell axis. This movement is obtained by means of a triple thread of ¼ inch pitch, giving a lead in one revolution of ¾ inch. Fitted to the head end of this screw is a short lever which is connected to a crank by means of a short link, the crank being attached to the end of a shaft which is revolved by means of suitable gearing to give the desired number of oscillations per shell revolution. The operation of this link motion causes the waving slide screw to oscillate through an angle of 60 degrees, which with a screw of ¾ inch lead, gives a side movement of ⅛ inch. The development of the wave is slightly different than that obtained by the face-plate cam method, but the variation is so slight that the holding power of the wave is not effected.



SPECIAL WAVE AND GROOVE MACHINE.

PRESS TOOLS FOR METAL CLIPS

By W. G.

THE accompanying drawings show a set of press tools which were gotten out for producing a limited number of the sheet metal clip shown in Fig. 1. Simplicity was aimed at throughout, consistent with satisfactory results.

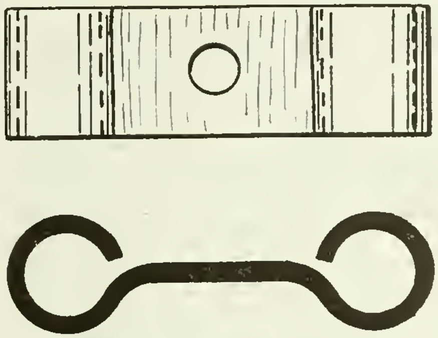


FIG. 1.

Piercing and cutting off the blank strip is performed by the punch and die shown in plan and elevation in Fig. 2. Die A is a rectangular block of tool steel in one end of which a slot A' is formed to act as a guide for cutting-off punch B. Guide plates C for the back of this punch are necessary to prevent it springing away from the edge of the die, and pulling piercing punch D out of alignment. Both punches are riveted in place in punch plate E, which is threaded to the shank as shown.

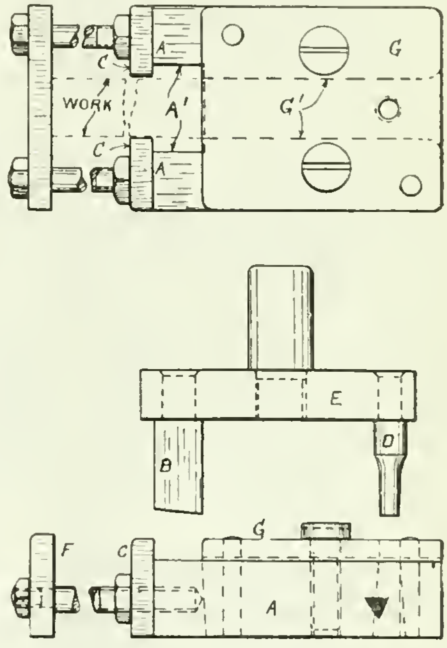

FIG. 2.

A stop plate F is carried by a couple of studs which also hold guide plates C in position. Stripping plate G is of mild steel with a groove G' on its underside for guiding the blank strip, the groove being amply deep to allow for unevenness in the strip.

Bending

Elevation and plan of bending operation are shown in Fig. 3, the die J being of case-hardened mild steel with a groove J' on its upper face for locating

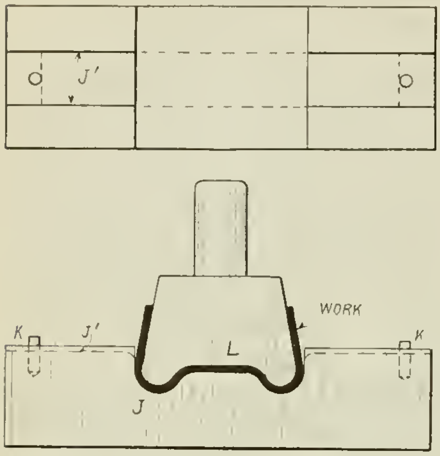

FIG. 3.

the flat strip which is centered by pins K. Punch L is also case-hardened, and has its end faces cut back past the vertical in order to produce a slight "set" on the work which assists the final or curling operation.

Curling

In Fig 4 are shown the curling dies. Lower die M has guide plates N on each side for holding plugs O in position. These plugs are inserted after the work is laid in position and are withdrawn to permit removal of the finished article. The ends of upper die P are extended to insure ample backing for the parts which come in contact with the work first; it is also made somewhat wider than the work so that the space between plates N will permit easy removal of the work.

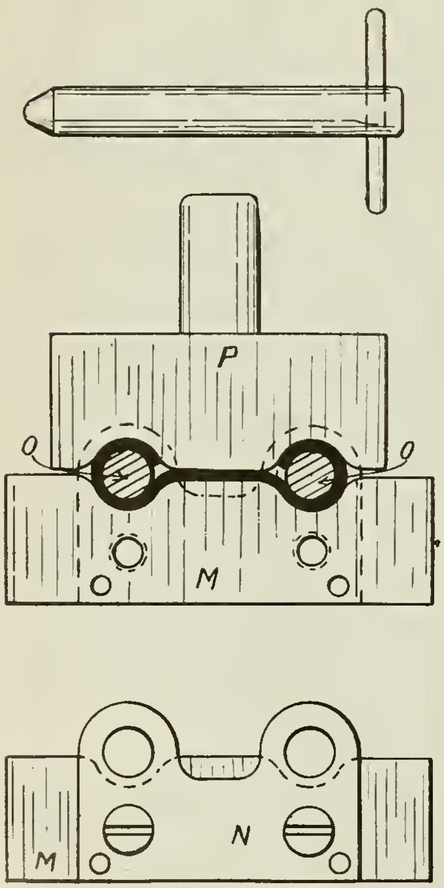

FIG. 4.

BORING AND REAMING LINE HOLES

By J. Wright.

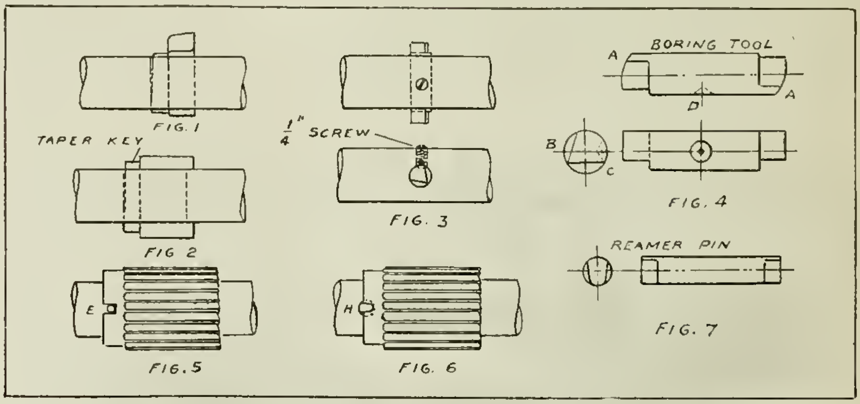
IN boring line holes in lathe heads, frames, engine beds, etc., the ordinary type of broached bar is used, and for the reaming operation either shank or shell-reamers are employed. The bar is placed on centres in a boring mill through the cored holes in the work, which is strapped to a carriage. The common type of cutters used are the single end square cutter, Fig. 1, fitting the broach in the bar, and the double end flat cutter, Fig. 2, both being held in position by a driven taper key. Two sets of cutters are required for the roughing and finishing cut.

The objection to the single end cutter is that it springs the bar out of truth, cutting as it does only on one side, it being left to the finishing cut and reamer to bring the holes again into alignment. Where two or more holes, supposed to be in line, are bored, it is impossible to make them line with this type of cutter, hence the introduction of the double-ended cutter to overcome this difficulty. These cutters, with few exceptions, work to better advantage. There is no clearance on the faces as on a single end cutter, and for this reason they have to be ground oftener and are soon worn out. They also require a fine feed as the cutting edges break easily, which makes them expensive wherever used. Driving the taper key in and out is another bad feature, as it springs the bar and upsets the centres.

little grinding and will not break. This latter fact is not to be overlooked for the reason that it will stand a much coarser feed in the roughing cut without breaking than can be taken with any other cutter. The cutters are made from drill-rod and since they are so cheap several should be kept on hand.

When they become worn down with a few grindings they should be thrown away and replaced with new ones. For holes less than two inches in diameter the cutters should be 5/16 inch in diameter. The lengths are turned the desired diameters and then backed off as A, Fig. 4; the angles, BC, Fig. 4, are then milled for proper clearance. Two sets should be used for roughing and finishing. A ¼-inch headless screw is sufficient for holding the cutters in position. The spotting D, Fig. 4, in the cutter for the point of the screw should have a liberal depth. The cutter should not be driven in the bar, but should be made free enough to move in and out by hand.

A slight improvement in the reaming operation has also been made. After the holes have been roughed out and the finishing cut taken they are ready to be reamed. This is usually done by placing a shell reamer on a shank and feeding it through the work by hand. The reamers are held to the shank by pins about ⅛ inch diameter that fit into the groove E, Fig. 5, on the end of the reamer. The pins are driven into the shank to prevent them from falling out. In order to get the reamers on the shank where different size holes are to be reamed, the pins must be removed. Constant driving with a drift and hammer renders the shank out of true, so that an accurate boring operation is sometimes spoilt by the reaming. To overcome this fault, a pin H, Fig. 6, is made so that it can be moved in and out by hand. Wire twice the diameter of that required in the first construction is used. The ends are milled



DETAILS OF BORING AND REAMING TOOLS.

Fig. 4 shows a new type of cutter, which as yet is little known. The small cost in making it is sufficient reason for its use, including the bar, Fig. 3, which requires only a round hole, also a tapped hole for headless screw to hold the cutter in position. The bar now used must be drilled and broached to fit both cutter and key. This type of cutter can be used on any class of boring in any metal, steel, cast iron, etc. It requires

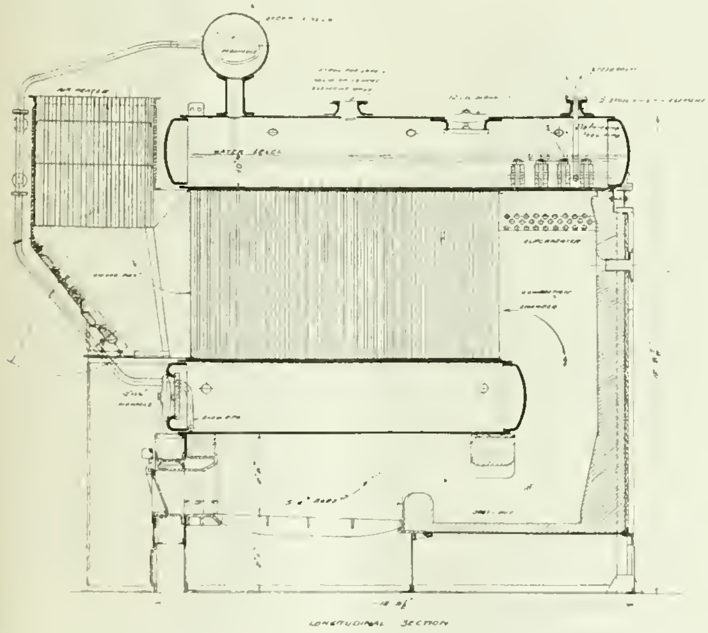
5 degrees tapering and the groove in the reamer also, Figs. 6 and 7, so that the reamer when tapped lightly with a piece of babbitt against the pin will fit snugly in the tapered slot, holding both securely on the shank.

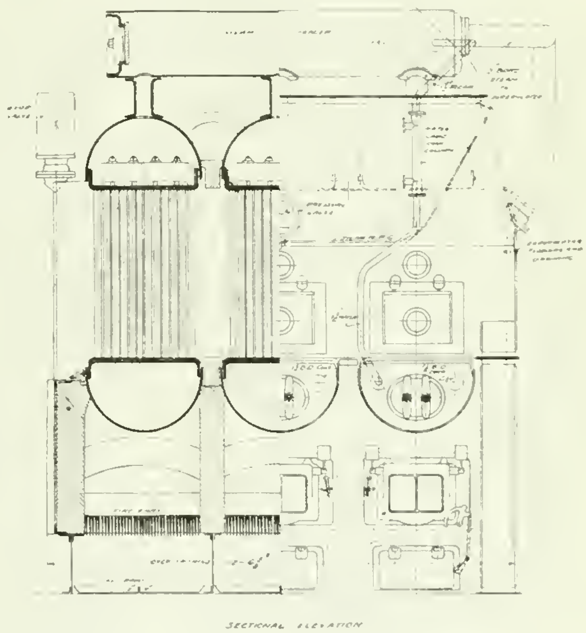
This method of manipulating the reamer, together with the improved boring tool is a step in advance over all other methods now employed in boring and reaming holes.

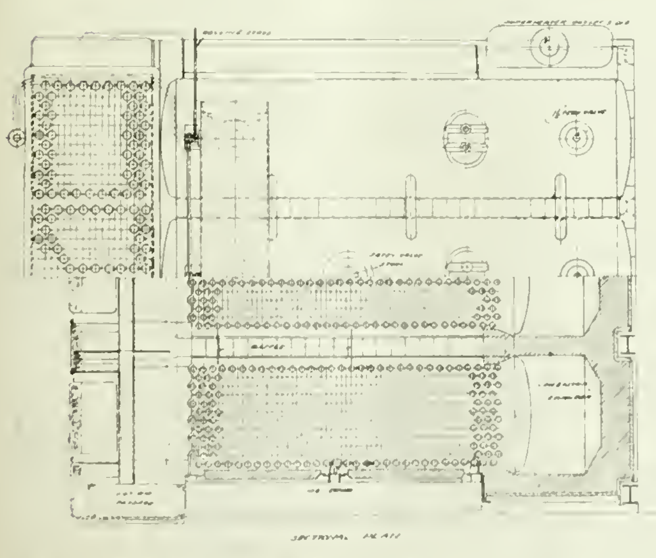
The "Howden" Sectional Type, Water-Tube Steam Boiler

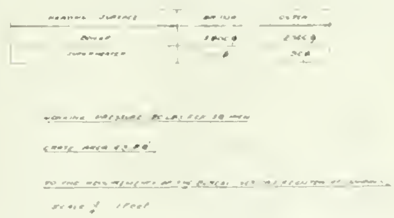
By C. T. D.

With the development of an intensive shipbuilding and marine engineering activity, there has resulted both a tendency and necessity to deviate from the beaten path in the matter of design and constructional detail of a number of the prime essentials entering into one or other, or both of the twin industries. The accompanying article features a type of water-tube boiler now being made in Canada, suitable for either land or marine installation, but which has hitherto figured but little, if any, as a factor in her steam engineering practice.









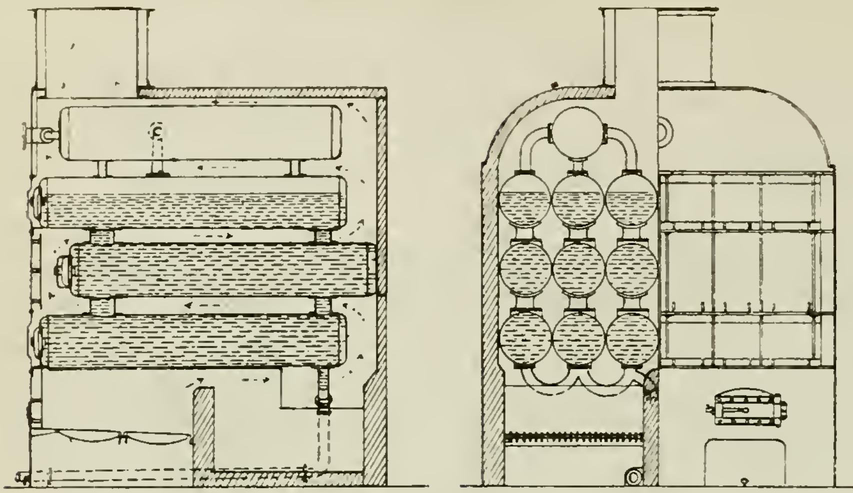
THREE ELEMENT "HOWDEN" MARINE TYPE WATER TUBE BOILER NOW BEING MADE IN CANADA.

THE "Howden" boiler as we find it to-day is a development of one designed in January 1861 by the late James Howden, of "forced draught" fame, and who in his lifetime was chairman of both James Howden & Co., marine machinery builders, and of the Howden Boiler Co., Govan, Scotland. As the date when the first Howden boiler was constructed occurred at a stage of marine engineering during which the use of high pressure steam for marine purposes took a sudden leap upwards, anticipating a progress which was not generally reached until fully 20 years thereafter, it will doubtless be interesting after an interval of some 56 years to chronicle the circumstances which initiated and led up to the present design.

In 1861, the usual steam pressures for marine boilers were from 20 to 25 pounds per sq. inch, beyond which it was not considered safe to operate with a salt water feed supply. Shortly before this period, however, several attempts had been made to introduce steam pressures of 100 pounds per sq. inch into steamships with compound surface condensing engines. Among these pioneers of the use of high pressure steam through compound engines and the use of fresh feed water, was the chairman of the Howden Boiler Co., who in 1859 contracted with the "Anchor Line" Steamship Co., to equip one of their Mediterranean fruit steamers with his then recently patented compound surface condensing engines and boilers to work with steam at 100 pounds per sq. inch. This steamer built by Alexr. Stephen & Sons, on the upper reaches of the Clyde, began to run in 1860, being successful and economical, running voyage after voyage without requiring overhaul or repair. Her boiler was as far as known, the first high pressure steam generator to operate successfully at sea in ordinary traffic continuously for a considerable period.

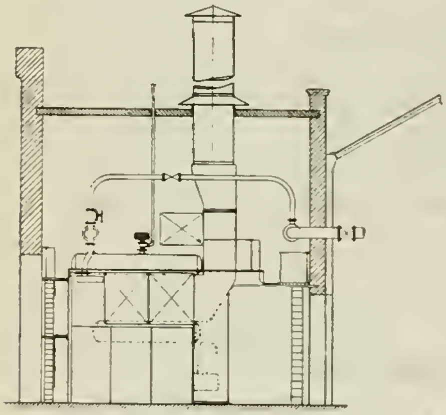
Another screw steamer ordered about

the same time by J. H. P. Hutchison for their trade between Glasgow and Bordeaux, and built by James R. Napier, F. R. S., at Govan, had compound sur-



ORIGINAL DESIGN OF "HOWDEN" BOILER, JANUARY, 1861

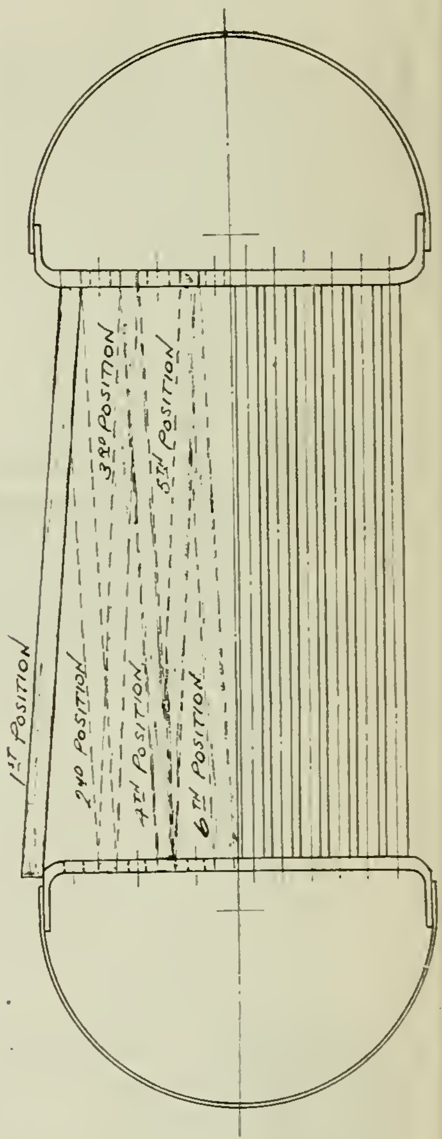
face condensing engines, also boilers using 100 pounds per sq. inch steam pressure, installed. Owing to the then design of the boiler, however, and the effect of salt water from a leaky sur-



SIDE ELEVATION OF "HOWDEN" BOILER INSTALLATION AT BOROUGH OF BERMONDSEY ELECTRIC LIGHT STATION

face condenser, this vessel never accomplished a voyage to Bordeaux and back without being laid up on account of the boiler requiring overhaul and repair. Inaccessibility for cleaning and repair were drawbacks to the boilers and, with a view to giving greater convenience in these respects, a new design was developed and gave satisfactory operating results, notwithstanding the fact that leaky surface condensers were responsible for abnormal incrustation of salt on the interior boiler surfaces. The accessibility procured limited materially the heating surface, hence rapid combustion, which progress in steamship engineering necessarily entailed, was more or less negatived. The subsequent evolution of the cylindrical multitubular boiler (Scotch), with its simpler style, and greater heating surface in same space occupied, evidenced a more economical design, and being, in addition, better fitted for the marine service of that period, naturally took pride of place, and still maintains a strangle hold.

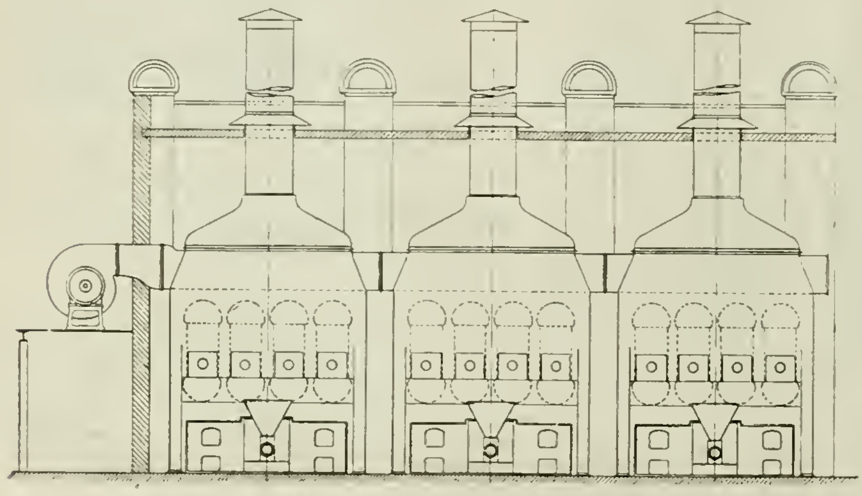
The present Howden boiler combines an evaporation from plate surfaces, as in ordinary boilers, with the addition of that from water tubes. It is now constructed under at least three patents—1908, 1910 and 1912, respectively, the last mentioned including a design specially adapted for high speed steam vessels, where lightness and small space occupied are of vital importance, or, for use on land in places difficult of access where the several parts can be carried by men or animals and put together without skilled labor under the direction of one competent engineer. All Howden boilers are designed to be equally suitable for land or marine services. As will be noted from the illustrations, covering boilers now being built by the Polson Iron Works, Toronto, who are the licensees for Canada, the individual units are simple in character, there being the minimum of detail parts,



METHOD OF STEPPING-IN NEW TUBES

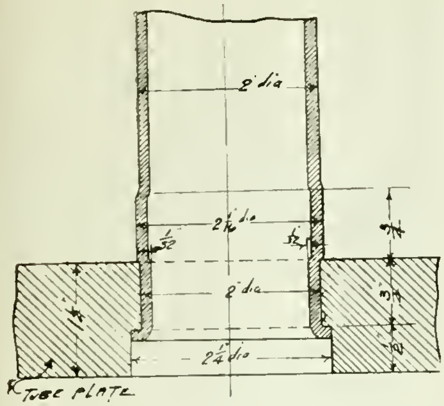
The worst possible position for a leaky tube is indicated. The intervening tubes are of course cut out and the new one threaded into position as shown. In consequence the holes are slightly larger in diameter than they were originally after expanding. This slackness allows the tubes to to be stepped into the various positions. The inner tubes require renewing at rare intervals.

while the sections or elements are duplicates of each other. One boiler may consist of one, two, three, four, or more elements, all the details of which lend themselves to repetition and duplicate work, therefore all parts can be made by special machinery to standard gauges, ensuring accuracy of duplication and good workmanship. The Howden boiler is adapted to work safely and economically under the highest air pres-



FRONT ELEVATION OF "HOWDEN" BOILER INSTALLATION AT BOROUGH OF BERMONDSEY ELECTRIC LIGHT STATION sure of the Howden system of forced draught, and at the highest steam pressures now employed.

All parts of the boiler when working are under an equal heat, that is, no one place is hotter or colder than another, while, in raising steam from cold water, all parts are brought under heat at the same time. The design lends itself to a rapid positive natural circulation without piping or other adjuncts, also to internal self-cleansing in the water tubes and drums where the water is in continual rapid movement over the surfaces exposed to the hot fire gases. In the matter of accessibility, attention is called to the fact that in a four element boiler, by the removal of eight manhole doors, the whole of the internal working parts of the boiler, that is, top and bottom drums and tubes, are at once open for examination when necessary. The fact that the tubes are short and straight is a matter of much importance, as they can all be examined in each element in a few minutes. For outside examination, the side portable doors can be quickly opened or removed, also the smokebox doors; and further, the combustion chambers are accessible by manholes from their underside, from which the back and tubes can be examined. Tubes can be removed and replaced quickly, the method of doing so being illustrated, as also the scheme of their fixing in the drum tubeplates.

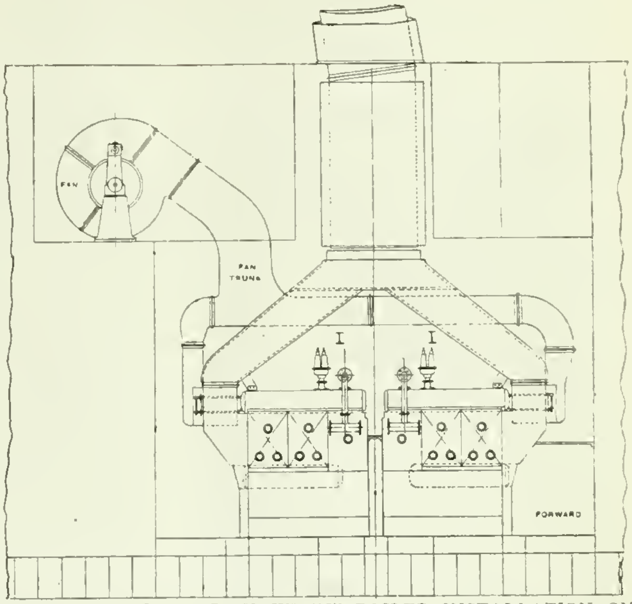


DETAIL OF TUBE FASTENING IN TUBE PLATES

Tubes cutter and extractor should be used for withdrawing tubes when possible, but if hand chisel be used, great care must be taken so as not to injure tube plates.

In the fitting of Howden boilers into steamships, important savings are effected. Vessels which are to have cylindrical boilers installed cannot be finished completely at the yard in which they are built, as marked spaces in decks and upper works above the boiler rooms must be kept open, not only for purpose of lowering heavy cylindrical units into place by crane after launching, but the work must be finished in such a way after the boilers are on board that these decks and upper works may be opened up again to remove the boilers when they are worn out or damaged, which always takes place after a longer or shorter period of service, and in order to refit the vessel with new boilers. In large high power steamships, the cost of opening up and reclosing deck work, etc., together with that for crane service, amounts to a large sum. In the case of the Howden boiler, the several parts can be put on board by either the shipyard derricks or those of the vessel herself, being afterwards lowered to place for erection, through the stockhold latchways or the funnel opening.

The Howden boiler may be equipped with chain grates or other mechanical stokers for land installations and may be operated under either forced or natural draft, although necessarily only with the former can the highest economy and power be obtained. The boiler patents include a superheater of simple and efficient design integral with the structure of each generating unit, also a feed heater or water back forming part of the boiler evaporative surface, which is specially suitable for naval installations where reduction of weight and increase of tube surface and power in a given space are of material importance. When superheated steam is not required, the superheater can be immediately converted into ordinary heating surface, and thereby increase further the evaporative capacity of the boiler. From the illustrations accompanying, no difficulty will be experienced in grasping the detail features which go to make up either individual or combination units.



SIDE ELEVATION OF "HOWDEN" BOILER INSTALLATION ON BOARD SHIP.

Test of No. 1 "Howden" Boiler

Heating Surface	3,125 sq. ft.
Grate Area	54 sq. ft.
Duration of Test	6 hours
Coal Burned (Bituminous Scotch)	11,058 lbs.
Coal Burned per Hour (average)	1,803 lbs.
Coal Burned per sq. ft. Grate	34.1 lbs.
Total Ash and Clinker	1,120 lbs.
Ratio of Ash and Clinker to Coal Fired	10 %
Total Water Evaporated	107,100 lbs.
Water Evaporated per Hour (average)	17,850 lbs.
Water Evaporated per lb. of Coal as fired under 192 lbs. pressure	9.68 lbs.
Water Evaporated per lb. of Coal as fired from and at 212 degs. Fah.	11.38 lbs.
Water Evaporated per lb. of Combustible at 192 lbs. pressure above atmosphere	10.7 lbs.
Water Evaporated per lb. of Combustible from and at 212 degs. Fah.	12.58 lbs.

Steam Pressure ...192 lbs. per sq. in.
Feed Temperature entering Boiler (Water Heated with Live Steam from Boiler).. 97 degs. Fah.
Temperature of Water in Feed Tanks .... 59 degs. Fah.
Funnel Gas Temperature ....473 degs. Fah.
Temperature of Gases Entering Air Heater 545 degs. Fah.
Temperature of Air in Reservoir ....196 degs. Fah.
Atmospheric Temperature at Fan .... 72 degr. Fah.
Air Pressure at Fan ....2⅝ inches
Air Pressure in Ashpit ....1¼ inches
Air Pressure in Furnaces .... ½ inch
Moisture in Steam (by Barrus Calorimeter.....About 1%
Flue Gas Analysis, CO_2 ....14.8 %
Flue Gas Analysis, CO ...... Nil.
Flue Gas Analysis O. 4%

Funnel 3 ft.-8 in. in diameter, 34 ft. in height above uptake, and 50 ft. above fire grate.

Steam was disposed of during the trial by blowing off into the atmosphere. Ashes were cleaned from ashpit forty minutes preceding the start of the test, and all observable clinker removed at that time. The fires burned freely, very little smoke being observed, and that only when firing.

BALL BEARINGS IN THE WOODWORKING INDUSTRY

TEN years ago ball bearing woodworking machines were a luxury. Very few were in use, because they were not needed, but labor cost began to climb and with it the construction of woodworking machinery underwent a complete change. Manufacturers demanded more work; production had to be increased to offset high expenses. This meant that each machine had to work at higher speed, and with heavier cuts. Immediately there was trouble. Bronze bearings which had been satisfactory, showed unexpected weaknesses. Hot boxes, burn-outs, and rapid wear were the rule. Evidently it was necessary to find some type of bearing which would stand up under heavy duty. After considerable experimenting some manufacturers turned to ball bearings, and their doing so marked the advent of ball bearings in woodworking machinery. From the very start they proved their ability to stand up to the most exacting requirements. Aside from this, however, ball bearings brought a host of advantages, among which were better work, more work, less power, less oil, cleanliness, freedom from hot boxes, reduced fire risks and lasting accuracy.

The advantages of ball bearings for woodworking machinery are: Reliability at high speeds; increased production; improved quality; accuracy of bearing detail; reduced maintenance; reduced number of accidents; bearing troubles minimised. A brief consideration of these points will prove each advantage clearly.

Reliability at High Speeds

It is plain that ball bearings would not be used if they were unreliable at high speeds, because makers and users demand speed. Ball bearings were tried when bronze bearings failed. After ten years of real service they are in use in most types of woodworking machinery and this is the proof of their reliability at high speeds.

Increased Production

A knife rotating 8,000 r. p. m. makes many more cuts a minute than a knife rotating 5,000 r. p. m. This is one reason why ball bearings increase production—they allow higher speeds and more cuts per minute. It has also been found by practical experience that ball bearings give a great reserve power to the machine by reducing the power wasted in friction, therefore, machines equipped with ball bearings can take heavier cuts. This is particularly noticeable in such machines as planers and shapers. A ball bearing shaper will easily take cuts that are heavy enough to stall a bronze bearing shaper

Improved Quality of Work

Users soon found that the quality of work done on ball bearing equipped machines was better and more uniform than that done on plain bearing machines. There are reasons for this. First, ball bearings are extremely accurate; a wheel, a cutter cylinder, or an arbor mounted in ball bearings can be adjusted with a high degree of accuracy. Second, ball bearings are self-aligning; any bending of the shaft is taken up by them. The bearing itself is so constructed that, without any special housing, it will compensate for shafting that is out of line. It is also practically impossible to bind a ball bearing; the shaft runs freely in any position. It is well to remember this, because no matter how much care is taken, sudden loads and uneven pulls will cause bending and deflection of shafts. High speed also improves quality because high speed means more cuts per minute, resulting in cleaner cut work.

Bearing Detail Accuracy

Ball bearings are made of high-grade materials, heat-treated in the most modern way and ground accurately to the ten thousandth part of an inch. The accuracy is lasting. Hardened steel balls rolling on hardened steel races practically eliminate all wear. Ball bearings put in woodworking machinery in 1907 are running today and are still giving the same care-free, reliable service, as when new.

Reduced Maintenance

Due to their low friction, ball bearings are very economical to use. The power saved can be turned to other work and the saving made will show up in actual money. Ball bearings save oil. They use very little, only a small fraction of the oil used by plain bearings, the bearing being so housed that it will hold enough oil to last for months. Furthermore, the housing is oil-tight, so no lubricant can be lost by leakage. An oil tight housing also means a clean machine, a clean plant, protection from fire risk due to oil soaked waste and "live" belts unspoiled by oil.

Belts on ball bearing equipped machines last much longer, because they do not run high tension, and are free from oil. Also, the machines start easily, the bearings do not stick, and there is no excessive tension when starting. All of the above help materially to lengthen the life of belts. If motors are equipped with ball bearings, another big saving is effected. The motors use little lubricant and are largely free from many troubles that often tie up production. Ball bearings are practically wearproof, so there is no need of replacing worn bushings. The danger of worn bearings allowing the armature to touch the pole pieces is in consequence entirely avoided.

Reduced Number of Accidents

Poorly adjusted bearings, play, hot boxes, pools of oil—all are frequent causes of accidents or fire, and all are eliminated by ball bearing installation. The parts are carried in correct adjustment and the bearings themselves are non-adjustable; no adjustment is necessary. Play is the result of wear. Hot boxes may be said to be unknown where ball bearings are used. The bearing is constantly bathed by oil, and since there is no friction there is also no heat. Fires from this source are therefore effectually prevented. Another source of fire is oil-soaked waste. Sawdust or shavings soaked with oil have been the start of many fires. By using ball bearings, housed perfectly oil-tight, this danger is removed. Pools of oil that collect dirt and leave slippery spots are a constant source of danger.

Some of the advantages mentioned here are more important than others, also some of them are more marked in one type of machine than another; but no matter what the machine is, the service and advantages gained by equipping it with ball bearings are certain and great. A prominent manufacturer of woodworking machinery who is a large user of ball bearings has expressed his opinion very clearly in one of his folders, thus:—"Steel ball bearings have so many advantages over both bronze and babbitt bearings then the manufacturer who once uses them will be satisfied with nothing else, provided of course that the ball bearings in the particular machine he is using are of the highest grade and of the best type procurable."

Nationalization in India.—A notification has been gazetted in India providing that where the output of any mine or industrial concern can be utilized in connection with the present war, the Governor-General in Council may require the owner, or any person in charge of such mine or industrial concern, to place it at the disposal of the Governor-General, who may use it in such manner as he may consider necessary or expedient.

MACHINISTS' INSTRUCTION COURSE—XXI.

By J. Davies

THERE is quite a number of difficult ways of setting up a milling machine for round work held between centres, that is, to set the cutter central, but it cannot be said that any

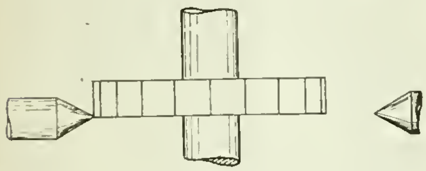

FIG. 78.

particular method is the best. A method suitable for one job, might be altogether unsuitable for another; it depends on the character of the work and the degree of accuracy required. A method that is near enough for some jobs is to bring the edge of the cutter in line with the point of the center before the work is put between the centers, then move the table over, half the thickness of the cutter Fig. 78; this will bring the cutter central. A slower but probably a more accurate way, is to start up the machine and take a few small cuts across the work, until you have machined a spot the width of the cutter. The cutter is now set central with the spot machined and will be very nearly central with the center of the job Fig 79—or you may set a try square on the table against the side of the work, and adjust the cutter until it calipers the same distance at each side from the edge of the square to the side of the cutter, Fig. 80.

Straddle Mills and Gang Cutters

Straddle mills are usually adjusted for width by placing washers between the cutters. Never use more than one washer, collar, or distance piece if it can be avoided—fine adjustment can be obtained by using paper washers. Adjustable distance pieces are sometimes used, that is one piece threaded with a fine thread to fit inside another piece, but

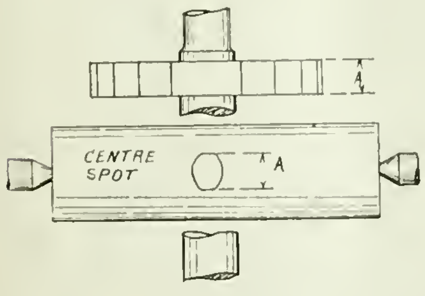

FIG. 79.

it is preferable to have a plain solid distance piece. It is necessary that the washers should be true sideways that is equal thickness all round. If not, when they are tightened up on the arbor the cutter will be untrue. In placing gang mills on the arbor put them on in such a manner that the cutting edges will not be in the same line—this distributes the cut better, breaks up the chips and is easier on the machine.

Taper Work Between Centers

The correct way to set the centers for milling taper work, is to have the axis of the index head spindle, coincide with the axis of the dead spindle irrespective of their relation to the line of motion. When this is the case the work will always be in true alignment with center, there will be no side motion to the tail of the dog during the revolution of the work and it will be possible under these conditions to divide tapering work into equal divisions. In some cases it is not possible to set the centers correctly in line owing to the construction of the center attachment.

When the axis of the work and the axis of the index spindle are at an inclination to each other, we have the same condition as in the lathe when turning taper with the tailstock set over, instead of using the tapering attachment. This has been fully described under the heading of lathe work; suffice it to say here that when the angular movements of the work and index spindle are not equal, it is impossible to obtain equal divisions. It is necessary to fasten the tail of the dog with a set screw to prevent any lost motion. When there is any axial movement to the tail of the dog, as there would be in the case just described, it is necessary to loose the set screw before moving the work and tighten up again after moving the work around the required amount. This will prevent springing of the work, but will not ensure equal divisions.

In some designs of index heads and tailstocks, the index head can be moved around in a circle, or part of a circle and is raised to point upward. The tailstock spindle has an adjustment up and down and may be raised until it coincides with the axis of the index spindle; that is to say when the axis of index spindle and the axis of the work agree, correct divisions may be obtained independent of the alignment of the tailstock center, Fig. 81

Aligning Work With Spindle

A very simple and practical method to test the alignment of the work with the index spindle is as follows: Put the face plate on the index spindle, and a common lathe dog or clamp on the work. Fasten the dog on to the work and adjust it so as to leave just room enough to pass a piece of paper between the end of the dog and the faceplate. Turn the work round and try the paper at each quarter turn, adjusting until the tail of the dog pinches the paper with the same degree of tightness at each point, when the work must of necessity be in line with the index spindle. There is one precaution to be observed in a set up of this kind. When machining a number of pieces supposed to be all alike, the least variation of length, or even in the depth of the center holes, will throw the work out of line, and cause the divisions to be unequal and the taper different. In most cases of repetition work the amount of error would be a negligible quantity but if the work were required to be as accurate as possible, every separate piece would have to be tested. If the cut is to be taken parallel to the surface of the work, that is a cut of equal depth, test with a surface gauge from the table before starting the cut. If the cut is to be deeper at one end than the other, just touch with the surface gauge or the cutter itself at the high end, then try the other

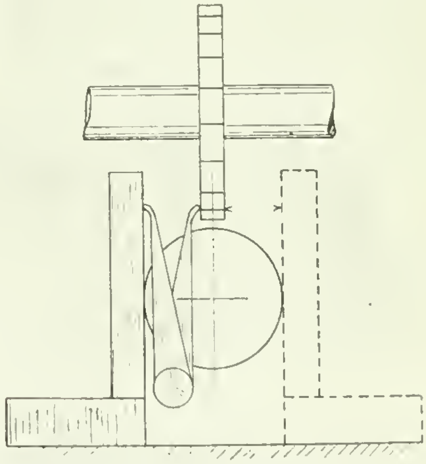

FIG. 80.

end and measure or caliper the difference; or make a little wire gauge to represent the difference of the depth of the cut, and place the wire gauge under the pointer of the surface gauge at the low end, letting the gauge just touch the work at the high end.

Indexing

When a piece of work must have a definite number of cuts taken across its surface, such as a gear with a certain number of teeth, or a reamer or anything that needs to be accurately divided, the index head is invariably used. There are many designs of index heads varying in details and arrangement, but the principle involved is common to all. A worm and worm wheel are usually employed, so that it requires 40 turns of the crank which is fastened to the end of the worm shaft, to rotate the work that is between the centers one revolution. In order to measure parts of a revolution, an index plate is fitted to the end of the worm shaft, but does not rotate with it, being prevented from doing so by means of a stop pin fitted to the frame. This plate has a number of concentric rows of holes, and in each row a different number of holes. The crank is adjustable up and down and can be made to coincide with any one row of holes, and is kept in position by a spring latch pin which is fitted to the crank. Most manufacturers supply tables with their index heads that give most of the divisions required. but every mechanic ought to know the reason why and be able to figure it out for himself. Although as just stated they are usually constructed so that it requires 40 turns of the worm shaft for one of the job, this is not necessarily always the case.

Figuring the Holes

The first thing to do is to find out by actual trial the number of revolutions for one turn of the work. Let us suppose that 40 revolutions of the worm shaft give one turn of the work, then it is evident that one turn of worm shaft would give 1-40th of a turn of the work and would divide the work into 40 equal parts. From this we deduce the following rule: Divide 40, (or the number of turns required for one turn of work) by the number of divisions into which the work is to be divided, and the resulting fraction will give the number of turns, or parts of turns which the index crank must make to obtain the desired result. Example.—It is required to cut a gear with 20 teeth; then according to rule, 40/20 = 2, complete turns. Example 2—How many turns must the crank make to divide the work into 12 equal parts 40/12 = 3 4/12 or 3 1/3. The question now arises how can we tell when we have moved the index crank around 1-3. After reducing the fraction down to its lowest terms, select a circle that is divisible without a remainder by the denominator of the fraction. Multiply the number of holes in this circle by the fraction, to obtain the number of holes the crank must be moved for the fractional part of a turn required. Thus 40/12 = 3 4/12 or 3 1/3. According to rule select a circle divisible by the denominator of the fraction 1/3, that is 3. Suppose we use the circle with 15 holes, then the number of holes required for the fractional part of the turn would be 15/1 × 1/3 = 5 holes. So that by using a 15 hole circle the right division would be 3 complete revolutions and 5 holes.

To Prove Calculations

Since every job will be completed when the index crank has made 40 revolutions, multiplying 40 by the number of holes in the circle used, will give the total number of holes used to complete the job, which in this case would be 40 × 15 = 600. Now divide by the number of holes used for each division, in this case 15 × 3 1/3 =50. The result will give number of divisions 600/50 = 12 divisions.

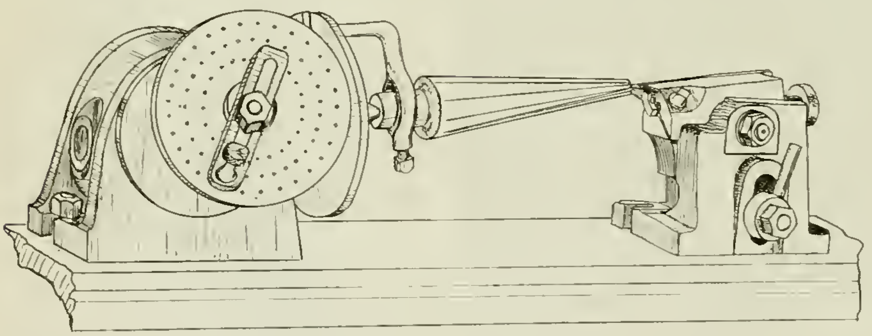

FIG. 81.

MATERIAL AND MECHANISM

By A. L. Haas.

THE entire economy of the mechanical profession divides neatly into halves, and the problems represented are nearly equal in value. Which section is the most important it is difficult to say and, indeed, perhaps idle to conjecture.

The ramifications of mechanism are well nigh inexhaustible; though, in the hands of a capable exponent, nearly every combination is reducible to a relatively small number of well-known elements.

The material field has been greatly broadened in recent years, yet it is this end of the business which presents many awkward problems to the machine shop.

An average engineer or designer, though directly concerned with materials, has generally little to do with its production. He is concerned with quality and choice, not with material as such, and hence is a selector only.

Science Aids Commerce

Purchasing departments are mostly concerned with the consideration of costs and their attitude is commercial. From dearly-bought experience, many large concerns now enlist the services of the metallurgical expert who can chemically and physically exert a check upon uniformity and desirable qualities. It is a business needing tact and discrimination, and the pure scientist is apt to discover the need for a commercial aspect to his work. Obviously nearly anything may be had at a price, but uncommercial material is usually at prohibitive prices. The desired qualities are uniformity, ease of working and similarity.

Coming to a more practical view of quality, or rather a quality,—hardness is relative both with regard to temperature and ingredients, method of working in production, etc., and is the product of a series of complex phenomena. Coupled with fragility under shock and unstable internal stress, it may at times be an undesirable element.

One fact comparable to the conservation of energy, theory is a realized fact today A single quality, in a superlative degree, in a material can only be obtained at the expense, and by the sacrifice of, other qualities. Nor can the steel maker, held to a rigid analysis, be expected to furnish material with rigid physical characteristics. If the physical qualities—tensile strength, elongation, reduction of area and yield point be specified, it is folly to add to these the chemical ingredients and hold the maker to both sets of test conditions. You may have either, but not both. Yet the fact remains that orders are issued containing such impossible conditions. The maker of material has reason to dread their advent and in some instances refuse to fill both analysis and physical tests.

Losses Balance Gains

In a single material, without alteration of ingredient, if the tensile strength be raised, the elongation or reduction of area suffers. Cold rolling will do the trick and render the material more fragile because less ductile.

The outstanding metallurgical fact is that by the introduction of new ingredients in, sometimes, minute quantities super-excellence in some one direction is assured.

Perhaps we are on the eve of obtaining by such application of research, materials with dependable qualities in two or more directions. The materials at present relied upon are specialized to particular ends.

We know little after all of the basic composition of matter, and however physicists theorise, it seems one of the most elusive of problems and as yet far from solution.

HOW THE MOVING PICTURE FILM GETS ITS MOTION

By D. A. Hampson.

A MOTION picture film is a celluloid strip about $1\frac{1}{2}$ ins. wide and hundreds or thousands of feet in length, crowded its whole length with thousands of small negatives, just the same as would be made in a little camera of $\frac{3}{4}$ in. x $1\frac{1}{4}$ in. size. There are sixteen of these negatives to a foot of length, and so rapidly have they been "snap-shotted," we will say, that a careful observer can see little if any difference between any of the sixteen in a given foot; it is only when a comparison of negatives quite a distance apart is made that a difference is noticed and one begins to comprehend that a progression is occurring and a scene is being unfolded.

The person who, for the first time observes what slow progress he makes with a scene when looking over a film in his hand, cannot fail to appreciate the rapid rate at which the film must run through the projecting machine in order to reproduce the scene in a life-like manner.

Not a Magic Lantern

Most of us have a general idea that this machine is a sort of glorification of the magic lantern of our youth brought up to date by electricity and mechanical

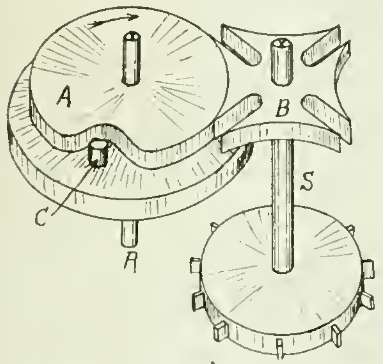

FIG. 1. DETAIL CONSTRUCTION OF GENEVA STOP MECHANISM.

movements so wonderful that it takes a skilled operator to run one. It is very true that if a film is in the machine and is held stationary, a picture from that negative will be thrown upon the screen just as would one from our primitive lantern slide—a noticeable difference being that the film is run through in and up and down direction instead of horizontal. Moreover, in the modern machine the firm travels at a rate that carries about 800 individual negatives per minute through it—a rate so high that without some very ingenious mechanism intervening there would be nothing but a swath of blur moving down the screen. What, then, is this mechanism that rises superior to blur and high speed and countless pictures having no perceptible difference?

What is called a "Geneva" gear is the important part of every projecting machine; it is a motion that (through the aid of other parts) draws the film along, stopping it momentarily when each picture or negative is in front of the lamp only long enough to allow a clear enlargement of it to be thrown on the screen and then, with a jerk that is discernible to the spectator only as a slight flicker, draws it just the height of another negative and brings it to a positive stop. This is done eight hundred times a minute, thirty minutes at a stretch, and always ready for the next roll. This Geneva gear is indeed a triumph, but not a modern one except in its refinements, for in textile mills we find looms bearing a date long "before the war" that are still doing business with the original Geneva in a fair state of preservation.

Action of Geneva Stop

Referring to the drawing, R is a shaft driven at a constant speed all the time, carrying one member of the Geneva gear A, which through the pin C drives a member B on the shaft S, which in turn draws the film through the machine. But while the shaft R revolves four times, the shaft S has made but one revolution and during that one it has been started and stopped four times—this is the motion that is transmitted to the film.

The member A is a disk whose periphery is broken for a short section opposite the pin C, which is rigidly set in the flange of the disk. Concave faces on the member B rest against the periphery of A, and during this period of rest, the shaft S and the film are stationary. Between the concave faces are slots, and as the disk A revolves, the pin C runs into one of them, moving the (so-called) star wheel B a quarter revolution. The movement of B is only possible because of the cut-out section of A opposite the pin. This is the motion that runs so faithfully hour after hour. Of course, the materials have to be of the best, the gears run in oil, and the shafts set for perfect meshing of the parts: in its present perfected state it looks very simple. The gear and shaft ratio is varied on different machines, but the one shown of one to four is generally used.

Location of Stop Gear

To make the working of the machine a little more clear, a part of the related mechanism is shown in Fig. 2. Here is shown a portion of the main frame of the entire machine, and also the oil-tight case enclosing the Geneva gear. The same intermittent shaft S extends out from the case and carries on it two sprockets which have a special form of teeth engaging holes in the film. There is a row of these holes of exactly the same spacing on each side of every film made and it is by means of these holes and sprockets that an accurate, positive movement of the film is obtained from the equally positive Geneva gear. This describes the salient features of the motion picture projecting machine of today; there are gears and lenses and

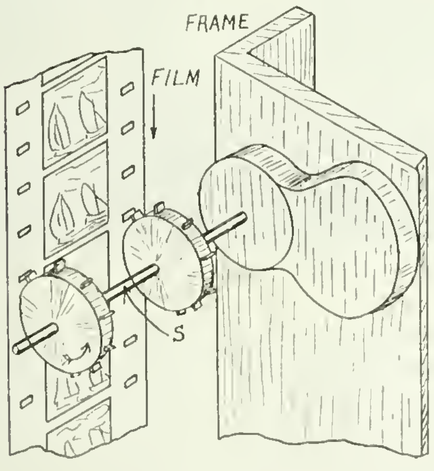

FIG. 2. SHOWING ARRANGEMENT OF GENEVA STOP MECHANISM AND FILM.

lamps and fire shutters, but they are of only passing interest. It might be added that one of the heaviest losses of the films themselves occurs from tearing, which comes from the action of the metal sprocket teeth jerking the light strip of celluloid. A torn film is valueless and though inventors have worked on some other forms of positive drive, they have so far been unsuccessful.

THE FUEL VALUE OF PITCH

By O. C.

BEFORE the war a very large part of coal tar pitch produced in Britain was exported, but since August, 1914, this outlet has been more and more restricted and the consequence is that huge accumulations of pitch are encumbering the working up of high explosives, munitions of war at coke ovens, gas works, and other tar distilleries. Prospective new outlets for use in gas and briquette making have not yet materialized to any appreciable extent, and as the rate of output is now more than 1,000,000 tons a year, the possibility of using pitch as a fuel for steam boilers and other furnaces demands consideration. Not only is its calorific value, viz., 15,500 to 15,500 B.t.u. per lb.—higher than that of the best quality Welsh steam coal—but its present price in the Midlands and London districts respectively, is only about one-third to one-half that of such coal; moreover, it is practically pure carbon, and ash and moisture free, so that in whatever proportion it may be added to other staple fuels, more than an equivalent amount of such fuel may be released for sale export.

Obviously, pitch cannot be burned on fire-bars designed for coal. The chief difficulty experienced in attempting to burn pitch has been the low fusing and volatilising temperature common to all pitches; and the consequent tendency to separate carbon in the form of dense smoke. Compared with average bituminous coal containing 28 per cent. volatile matter, pitch contains about 55 per cent., the remainder being practically pure amorphous carbon.

Experiments have been recently conducted, however, with a view of arriving at a simple and inexpensive form of grate which would answer the purpose, and as a result it is claimed that a method has been found whereby coal-tar pitch may be consumed in conjunction with coke with considerably less than the ordinary amount of smoke observed at the chimney of a coal-fired boiler. The modus operandi, which has been tried with some success in certain gasworks boilers, is to substitute a number of "pitch" bars for an equivalent number of existing fire-bars in a boiler furnace fitted with steam jet forced-draft apparatus of ordinary construction. Pitch, broken to any convenient size, is fed on to the pitch bars, where the heat of the surrounding fire causes it to collect and volatilize; the rate of such volatilization being controllable by means of the special formation of the pitch bars, within limits which ensure practically smokeless combustion. The partially coked residue remaining after the more volatile constituents have been burnt off is periodically raked on the rear portion of grate, where its combustion is completed.

AN increasing number of useful organic drugs, including alkaloids, is now made synthetically from other chemical substances. Many of these are unknown in nature, their production and utiliz[illegible]n being solely due to science.

PLANT REFERENCE LIBRARY

A FACTOR likely to have considerable bearing upon the increased productive power of manufacturing plants, would be the establishment of a works library, in which a quantity of technical books and other literature would be available for ready reference for those officials who might be confronted with difficult problems pertaining to their particular class of work. These libraries would not require to be stocked with a wide range of subjects, but preferably a quantity of books and periodicals containing a comprehensive record of previous and current practice in the particular lines of activity in which the various plants are engaged.

While the available books would be primarily for reference purposes by the various department heads, the opportunity should be provided for the loaning of these books to any employee desiring same for study. By encouraging the workmen to take a greater interest in the technical features of their daily labors, it would not only increase their productive efficiency but also their earning power; and at the same time provide a means of developing trained men that would take a keener interest in the work they are doing. The returns from a reference library of this nature should more than repay the expense entailed by installation and maintenance.

EFFICIENCY THROUGH CO-OPERATION

APPARENTLY, the keynote of successful manufacture of the present day is based on the principle of efficiency, yet the fact that this efficiency must vary to a great extent in every individual and likewise every industry, makes it the more difficult to understand and also to define. From the dictionary we learn that the meaning is resolved into the ratio of the work performed to the energy expended, and while this applies more in the terms of mechanical work, the same is applicable to achievement of any or every kind. Individual efficiency, however, is the striving to accomplish what is required of you with the least expenditure of energy in the least possible time and with the most satisfactory results; and while this is true in the case of personal ability, the effect is the same in all lines of industrial activity, for the entire problem is mainly one where the human factor is the chief essential. With the individual, this trait of utilizing the full power to produce can only be acquired by stirring up the latent energies of the mind and body—the latter, in many instances, does not respond readily to the activities of the former, and adapting these energies to the best possible accomplishment of the desired objective. In the case of industries, great or small, maximum efficiency is only possible by the development and maintenance of this important factor in every individual workman.

Many manufacturing plants in the past have been impressed with the idea that their efficiency has been the result of adopting certain methods in the manufacture of their product, the secret of which they have been able to withhold from others in the same business, thus being able to advance more rapidly than the other. While this may be true in some cases, such an idea of efficiency is becoming exploded by the more broad-minded one of mutual co-operation and the interchange of ideas. If the old order of things had prevailed during the past three years of abnormal activity, every manufacturer relying on his or their own ability and resources for the development of the shell industry, the success of this industry would undoubtedly have been far below what actual results have proved.

The magnitude of recent munitions activity throughout the entire Dominion has clearly shown that to attain maximum efficiency both in the individual and in the operation of the plant, it was most essential that every facility be provided for maintaining production at the highest possible figure, and in order to do this it was found advisable, in fact necessary, to have a free and unrestrained exchange of thought and ideas regarding the best methods of achieving a certain end. It therefore follows that the highest efficiency in any line of endeavor can only be attained and maintained by the mutual co-operation of every one connected with the origination, progress and achievement, of every line of thought and action.

We speak of a machine in terms of efficiency, yet it depends almost entirely upon the operator what this term really implies. When a man is kept employed on a certain machine for any length of time, his effectiveness will naturally increase in proportion to the interest he takes in his work and also the nature of that work. If, however, the nature of the work is such that monotony is a feature of its continual operation, the efficiency of the machine may remain constant, but the actual production may be lessened, due to the laxity of the man working it. This has been offset to some extent by the introduction of the piecework system, whereby a workman is encouraged by possible additional remuneration for greater production. On the other hand, where the nature of the work calls for the closest concentration in the accomplishment of same, and where the accuracy of the work depends more on the operator than on the machine, the individual workman and eventually the shop in which he is employed, may find themselves traveling in a rut with their relative efficiency unchanged, but at the same time falling below that of the other plant which has brought itself to recognize the increased possibilities by adopting methods whereby certain operations can be improved or production increased.

Efficiency is a flexible term when applied to production; its value may change from day to day as a result of many causes or a combination of several, but it is safe to say that the chief essential in maintaining a constant and gradual increase in operating efficiency is the closer co-operation of individual activity and the freer interchange of ideas between the men in each shop and with those of other shops, the latter being made more effective through publication in the editorial columns of their trade and technical journals.

INDUSTRIAL NOTABILITIES

WILLIAM EVELYN VALLANCE, director, Carbon & Alloy Steels, Ltd., Hamilton, Ont.; director, Wood, Vallance & Leggatt, Ltd., Vancouver, B.C.; director, Wood, Vallance & Co., Ltd., Winnipeg, Man.; director, Ontario Motor League, was born in Hamilton, Jan. 27, 1884, son of William and Marie (Phelps) Vallance.

After receiving his education in private schools at Hamilton, and Trinity College School, Port Hope, Ont., Mr. Vallance began his business career with Wood, Vallance & Co., Hamilton, 1901-1916.

In the latter part of 1916 Mr. Vallance, along with Mr. H. J. Waddie, President of the Canadian Drawn Steel Co., organized Carbon & Alloy Steels,

WILLIAM EVELYN VALLANCE.

Ltd., operations at present being carried on at the Moffat Irving Steel Works, Toronto, preliminary to moving that plant to Hamilton, where the production of alloy steel castings will be engaged in.

Mr. Vallance holds a commission as Lieutenant in the 13th Royal Regiment, Hamilton. He married Arvilla Adelaide Gurney, daughter of Charles Gurney, Oct. 19, 1910, the family consisting of two sons.

His societies are: A.F. & A.M.; while he is also a member of the following clubs: Hamilton; Thistle; Hamilton Golf; Canadian; Caledon Mountain Trout; Waterloo Golf & Country (Galt).

In politics he is Conservative and in religion, Presbyterian.

Mr. Vallance's residence is 228 Bay Street South, Hamilton, and his country home is "The Croft," Burlington, Ont.

The General Market Condition and Tendency

THE steady increase in cost of raw materials, particularly iron and steel, continues to be an important factor in the industrial situation. The increase in cost of production is reflected in the price of the finished article which is having a tendency to restrict sales and reduce profits. This unfavorable feature is unavoidable under prevailing conditions, but nevertheless creates an unsatisfactory situation for the manufacturer to contend with. The demand for steel is becoming more insistent and is considerably greater than the capacity of the mills. Deliveries consequently are getting more backward to the despair of the private consumer. Prices of iron and steel continue to climb and a sharp advance on sheets and plates is expected very shortly. The plate situation is very tight and some mills are refusing business. Prices of domestic foundry pig-iron have been withdrawn, owing to the sold-up condition of the furnaces, there being practically no iron available for delivery this year. The scrap metal market is firmer with prices maintained on the basis of last year's schedule. The non-ferrous metal markets are not very active, but prices are firm with the single exception of tin, which has declined. Copper, although quiet, is firm, while the lead market is unusually strong. The demand for machine tools is fairly active, being principally for equipment for general purposes.

Montreal, Que., June 2, 1917.—The curtailment in the manufacture of the heavier shells has enabled the labor situation to be somewhat relieved, but should conscription become an active factor in the mobilization of men for further war effects, the industrial situation will probably be faced with another problem in the maintaining of present activity in many manufacturing lines. Added to this will be the additional men that will be required for the shipbuilding program anticipated by this and other governments; this latter feature being one of the most essential of all.

Steel

War requirements are now taking precedence over all other industrial activities, and developments in the States are making it almost imperative for private enterprises to withdraw from the market, not only through the high cost of all classes of material, but also because of the practical inability to obtain it in face of rising conditions. It is anticipated that the steel demands of the American Government will be considerably greater than at first contemplated and producers are looking forward to the necessity of putting additional pressure on the mills to meet the additional requirements. This situation is more pronounced in sheets, and manufacturers of automobiles to a certain degree, are endeavoring to co-operate with the government in the curtailment of production of pleasure cars; this however will be more than balanced by the increased output of heavy motor trucks for use by the United States Government. The American shipbuilding programme has not been definitely settled and the probability is that much more steel tonnage will be placed under construction than at first supposed. Plate mills are working hand in hand with the authorities for the adequate supply of the necessary material and with the increased facilities that are being rushed to completion, the progress of building ships will be advanced as rapidly as possible.

The action of the American government in organizing for war activity has added to the difficulties of obtaining delivery of semi-finished and finished materials, as the authorities are securing preference for the transportation of ores and coal for the production of steel and iron requirements. The heavy demand for billets and sheet bars continues, more particularly for rolling and forging billets, and Pittsburgh quotations have been advanced $5 per ton, the prices being $95 and $115 per ton respectively. Increased demand has been noticed in structural steel, much of this being for enlarging the capacity of steel mills in various sections of the country. The position in plates is of most interest owing to shipbuilding needs, and the early future may develop conditions that will make it increasingly hard for domestic consumers to secure material. The local situation has become more acute with deliveries more backward; dealers have again revised prices, the advance noted this week being $20 per ton, the current quotations being $10 for ¼ inch to ½ inch plates, $10.30 for heads, and $10.10 for 3-16 in. tank plates. The tin plate interests are exceptionally busy and have been so ever since the declaration of war, as the requirements for tin plate to be manufactured into cans is exceedingly heavy. The same condition prevails in the case of sheets of every description for the making of various equipment for army and other needs. Higher prices are the undertone of the market; nominal quotations by local dealers have been revised, these having been somewhat stationary for some time. Black sheets 28 gauge, are now $10 and No. 10 is quoted $9.50 per hundred. Apollo brand, 10¾ oz. is now $9.75; Queen's Head, $10.75, the same price applying to Fleur-de-Lis. Colborne Crown No. 28 is quoted at 10 cents per pound. Wire products are in very heavy demand and a stronger market is not unlikely. Heavier business is reported in shafting and deliveries are being extended. The new list price on proof coil chains has been placed into effect by local dealers, the revised prices ranging from $10.75 for ¼ in. to $9.25 for 1 in.

High Speed Steel

The situation in high speed steel remains comparatively unchanged, although the total volume of business has declined a little owing to the curtailment in the production of the heavier types of shells. The demand for high speed steel however, shows no falling off in proportion to the requirements of the smaller shells and the encouraging increase noted from other sources. The price is well maintained, the quotation ranging around $2.50 to $2.90 per lb.

Metals

The general tone of the metal market is one of comparative quiet with a touch of uncertainty owing to the delayed action of the American government. An optimistic feeling seems to prevail however, and all the metals are firm with several showing a stronger tendency. Copper is quiet but quite firm. Tin is inclined to be easier on increased available supply. Spelter is not active but the strength is maintained by the reluctant attitude of the producers. Lead continues strong in spite of decreased demand. Antimony demand is normal with an easier price tendency. Aluminum remains firm and unchanged.

Copper.—The market is still influenced by the uncertain attitude of the government in defining the war policy and the copper requirements for early future operations. Despite the rumor that were current a week ago, regarding the production costs of copper smelting, the market has retained its strength, but has fallen off in activity and may continue so until more settled conditions offer a basis for future buying. The New York market shows a decline of ½c on lake and a similar advance on electrolytic, the quotations being 32c and 33c respectively. Dealers here continue to ask 38½c for lake and electro, and 37½c for castings.

Tin.—Considerable arrival of tin has created an easier market and prices have shown a slight decline. A feature of the situation, and one that tends to maintain an unsettled market, is the action of the American government in circulating forms upon which information is to be gathered to enable the committee to secure reliable data regarding the tin available for manufacturing purposes, and also the needs of the trade in connection with future requirements. The American market has developed an easier tendency and prices have declined one cent per pound, the current quotation being 64c. The local market is firm and unchanged at 62½ per lb.

Spelter.—The spelter market is in a very unsettled condition and in all probability will remain so until developments indicate the actual trend of affairs. Producers are reluctant to book future business, and prefer to accept spot or early positions at slight concessions on current quotations. Some producers are thought to have curtailed their output, preferring to await developments upon which to base their future operations. Producers declare that it is unprofitable to smelt the metal at the present prices and under existing conditions. The New York market has fluctuated a little during the week but the present quotation of 9⅝ is the same as last week. Dealers here are asking 13½c on a steady but easier market.

Lead.—The situation is this metal continues to be one of exceptional strength, and while the quotations would appear as being made by the large producers, the actual conditions are to the contrary. The New York quotations both by the Trust and the independent producers, are those at which certain sales can be, and in fact are, made on the open market, and while these large producers realize that this is true, they are nevertheless supplying their regular customers at prices lower than that prevailing in the open market. New York nominal quotations are 10c and 11½c for Trust and outside respectively. The situation locally is very firm on an active market, the price quoted being 13½c per lb.

Antimony.—This metal has taken on an easier tone owing to the recent dullness and prices show a weaker tendency. New York quotations show a decline of 1½c during the week, the present price being 23½c per lb. The local market is quiet and one cent lower, the price asked being 26c per lb.

Machine Tools and Supplies

No important change has taken place in the machine tool situation and conditions are about as usual. The American market is a little unsettled but quite active, and this condition will likely continue until the war policy is finally defined, when additional activity may mark the situation. What might be termed a regular feature of the market is the gradual but certain upward trend to higher price levels, a factor that must naturally follow the general developments of war conditions. Supplies are still in good demand and showing a heavier tendency, with prices inclining upwards.

Scrap

The market in old materials continues very active, the demand for steel and wrought iron scrap being very heavy. A feature of the situation is the apparent scarcity of cars, and all dealers, more particularly in the United States, are requested to see that cars are fully loaded when shipping to facilitate the handling of tonnage with the available equipment. All scraps are very strong, with steel and coppers developing a better undertone.

Toronto, Ont., June 5. — The outlook for manufacturers does not improve in spite of the fact that the volume of trade continues to increase. The shortage of raw materials, particularly iron and steel, is more pronounced and is causing serious inconvenience, as work is being held up. The situation as regards labor is not at all satisfactory. There is a decided scarcity of skilled help and the question of wages seems likely to cause trouble in the near future. The price of coal shows no indication of declining and radical measures will have to be adopted to prevent a serious situation this coming winter.

Steel

The situation in the steel trade is steadily becoming tighter and more complex. Deliveries are so far behind that private consumers are obliged to hold up all kinds of work because of the lack of steel. In this regard conditions are getting more acute owing to the tonnage of steel required for war purposes. Canadian consumers are feeling, more than ever, the effect of conditions in the United States. The American Government will require an enormous volume of steel which will curtail the available tonnage for Canadian consumers. Owing to the pressing demand for steel for munitions and war materials, Canadian mills cannot supply the domestic market. Because of the urgent need for steel rails in Canada, the Imperial Munitions Board has decided to release 25,000 tons of steel which will be manufactured into rails. It is understood that 15,000 tons will be supplied by the Algoma Steel Corporation and 10,000 tons by the Dominion Steel Corporation. With regard to the production of steel, the reports of the Dominion Steel Corporation furnishes some interesting figures. It shows a marked increase in tonnage for the year ending March, 1917, over the preceding twelve months.

Prices of all steel products are very firm and a number of important advances are expected very shortly affecting black and blue annealed sheets, and plates. It is likely that the next advance will be equivalent to one cent a pound. The plate situation is getting more acute. In view of the American Government's shipbuilding programme, the need of steel plates for this purpose will be very heavy and private consumers will find that deliveries will get worse rather than better. Owing to the rush of orders for plate, some mills are refusing the business. There is no change in the boiler tube situation and prices are holding firm. Wrought pipe is also very firm at unchanged quotations.

A large number of manufacturers of black sheets have withdrawn from the market because of the American Government requirements. The Government orders for sheets so far have been heavy and its requirements will likely be much larger than anticipated. The sheet mills believe that they will be able to take care of their ordinary trade fairly well but there will likely be serious delays in deliveries. Under the circumstances prices are bound to go higher and an advance is expected very shortly on both black and blue annealed sheets.

The steel market in the States is naturally very strong as the Government's requirements for steel are very heavy and will eventually involve an enormous tonnage. The situation as regards deliveries of nearly every form of finished material is tightening as the demand is increasing all the time and is far beyond the capacity of the mills. Prices continue to advance. Tank plates are now 7c. at Pittsburgh. Bessemer and O H. billets are higher, being now quoted at $95; O. H. sheet bars are also $95 Pittsburgh. Wire rods have advanced and are now quoted at $90 Pittsburgh.

Pig Iron

Prices of domestic foundry pig iron have again been withdrawn as the furnace operating on this grade of iron is booked up for this year. At Buffalo the market is steady yet, although the general trend of prices is upward, no material change has been made from the quotations reported last week. It is understood that the Canada Cement Co. is producing about 50 tons a day of high grade low phosphorus pig iron with the electric furnaces previously used for turning out shell steel.

Scrap

The scrap market is reasonably firm, but there is no very great demand. The buying movement reported a week ago lasted for a few days and then became quieter. Prices are unchanged but are generally firm and, if anything, have a higher tendency.

Machine Tools

There has been a slight revival of munitions activity in the form of light tools for fuse work, the equipment being purchased to increase production. A return to more normal conditions continues to be the principal feature in the machine tool market. Some nice business has been closed during the week by local machinery houses for equipment for general purposes. Developments in the trade in the States continue to be of a war-like nature and considerable activity is indicated.

Supplies

There have been no price changes of particular importance made during the week, but all quotations are holding firm. Advances were made in gasoline prices in the States in several districts during the past week which may be reflected locally. The crude oil shortage is growing more acute and prices on some grades have advanced.

Metals

Although the metal markets have not been particularly active during the week, prices are firm and have been maintained at last week's levels with the exception of tin, which has declined. The copper market is firm with prices still nominal. Spelter although unchanged has a firmer undertone, while lead continues in a strong position with a higher tendency. Both antimony and aluminum are quiet and situation unchanged. Metals in New York continue to be affected by prospective Government buying, which is still somewhat indefinite, and is tending to restrict business and depress the market.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the Commission headquarters are at Ottawa.

Copper.—Comparatively little interest is being shown in copper at the present time and the market is dull. The position of copper, however, continues strong and prices firm. Present high prices are bringing out small resale lots from consumers, but there is no great amount of copper offered by first hands before August. Local quotations are unchanged and are as follows. Lake and electrolytic 38c., and casting copper 37c. per pound.

Tin.—A decline in the price of tin in London has been followed by declines locally and also in New York. The reason for the decline on this side is said to be due to lack of interest in the market and fairly heavy arrivals of tin recently. Tin has declined 2c. locally and is quoted at 66c. per pound.

Spelter.—The market is dull and unchanged, but the zinc ore situation is strong, which indicates that a decline in spelter is unlikely. The market has a firmer undertone and prices might advance if the demand improved. Local price 12c. per pound.

Lead.—There is no change in the position of lead. The market remains strong owing to the fact that no lead can be had from the leading producers who have consistently remained out of the market for several weeks. There is some hope, however, that increased production during the next month or two will enable the producers to offer lead for sale. Local quotation firm at 14c. per pound.

Antimony.—The market is easier owing to lack of interest on the part of consumers, but quotations are unchanged at 30c. per pound.

Aluminum.—The situation is unchanged and the market remains steady at 68c. per pound.

Pittsburgh, Pa., June 2.—The average price of pig iron in the United States, f.o.b. furnace, on June 1, 1917, was about $43.75, against an average of $12 to $12.25 during the last two months of 1914 and the first six months of 1915. The average price of finished steel products, Pittsburgh, was about 4.59c., Pittsburgh, on the first of this month, against a low point in December, 1914, of about 1.42c. Thus pig iron is selling at nearly four prices and finished steel at more than three prices. Previous rises in 1912, 1909, and 1905-7, carried prices upwards only by from 25 to 40 per cent.

These extremely high prices were not due directly to war demand, but rather to the unsettlement caused by the war. It was not the ordinary case of demand and supply, as after a certain point was reached in the advances, production or supply was not further stimulated. There was no collusion among sellers, the case being simply one of buyers bidding the market upon themselves, actuated by fear that if they did not buy ahead they would be unable to secure material. The advances were made by the buyers rather than by the sellers. The individual seller would have simply placed himself at a disadvantage if he had refused to advance prices when higher prices were so readily obtainable.

Outbreak of War Depressed Prices

The first result of the inception of the war was to depress prices, already at a very low level. Finished steel prices began recovering at the beginning of 1915, while pig iron did not start upwards until July of that year. Until June, 1915, scarcely anyone seemed to realize that the American steel industry could become genuinely prosperous as long as the war lasted, but suddenly, by the end of August, it was realized that the steel mills were filled with orders and were operating practically at capacity. Then forward buying began on a large scale by all classes of consumers. By the end of 1915 steel prices had reached the top level attained in 1907, the highest reached since 1902. Then it was that the runaway began. There was a lull in buying and in price advancing towards the middle of the year, but, in August, advances began again and buying was correspondingly stimulated.

Upon the declaration of German unrestricted submarine destruction on February 1, the common appraisal by leading business men was that war for the United States would result. The pace of price advances became somewhat more rapid, and the pace was continued in April, after the actual declaration of war. During May the advance in steel products gradually tapered off, while the advance in pig iron, if anything, became a trifle more rapid.

The production of pig iron and steel in 1915 was approximately the same as in 1912 and 1913, the two years of heaviest production before the war. Production in 1916 showed an increase of approximately one-third, pig iron rising to 39,400,000 gross tons, steel ingots and castings to 42,800,000 tons, rolled steel to 30,500,000 tons and rolled iron to 1,800,000 tons. Production is now at the rate of more than 40,000,000 tons a year in pig iron, nearly if not quite 45,000,000 tons in steel ingots and castings, and about 32,000,000 tons in rolled steel.

Steel involved in exports, direct and indirect, amounted in 1916 to a trifle less than 8,000,000 tons, or not over about 25 per cent. of the output, so that the strictly domestic consumption of steel was materially greater than in any previous year.

Steel Prices Peak Reached

Evidences have been multiplying in the past two or three weeks that the advance in steel prices has practically come to an end. While somewhat stiffer premiums are ruling here and there on prompt deliveries than was the case two or three weeks ago, there have been no important price advances in the period.

There is a change in the attitude of buyers, who are reflecting that it is quite impossible to determine what will be the actual consumption of steel in the United States six or nine months hence, when the activities of the country will have been turned over completely to the prosecution of war. The rank and file of the people, who have been the consumers of steel in the past two years more than is usually the case, do not yet fully realize what the war means. As to investment buying, that has been relatively light during the war. The monthly reports of the Bridge Builders' and Structural Society have been showing fabricated steel lettings equal to only about two-thirds of the fabricating capacity. The car shops have been operating at only about one-half their capacity. The present attitude of jobbers and manufacturing consumers is that they should go slow in the matter of buying for forward deliveries, and if steel prices remain stationary as they have been lately there will be all the more occasion to follow this policy, as it is traditional that really heavy buying occurs only when prices are advancing.

Steel Prices Largely Nominal

Steel prices are largely nominal as the large mills are sold up very far ahead and to continue to take care of their regular trade they must refrain from quoting in the open market, while the smaller mills, able to make earlier deliveries, are quoting various premiums according to tonnage and delivery. Merchant steel bars for forward delivery are usually quoted at about 3.75c. to 4c. The Steel Corporation's official price is 3.50c., but even to its own customers it is selling only in a very limited way. Structural shapes are 4c. to 4.25c. What used to be the official price on tank plate is 4.50c., but even the Steel Corporation has sold at above that figure, and early deliveries have been bringing up to 7c., while ship plates to Lloyds' specifications bring 8c. or possibly 9c. for anything like early shipment. Sheets are 7c. to 7.50c. for blue annealed and black for forward delivery, if a seller can be found at all, with premiums for prompt shipment. The official price of the American Steel & Wire Co. on nails is $3.20, but if this price is named at all it is only to regular customers, and the independents, who advanced to $3.50 on April 23, are understood to be securing even higher prices than that.

In nearly all cases export prices are quoted higher than domestic and on much export enquiry there are no quotations obtainable at all.

Steel for Government

Practically no information is available as to prices on steel for the Government. Not a great deal of steel has been definitely placed, apart from that required for the 1917 naval program, some 450,000 tons, placed about the close of March, at 2.90c. for the plates and 2.50c. for the shapes and bars. It is not expected that subsequent purchasers will be at as low a level. There is a theory in some quarters that some of the steel manufacturers would prefer to see the whole steel market established at a lower level than the present one, which is not an established level—it simply exists— and that perhaps the fixing of prices for Government steel might tend to bring the market down to a basis which would have some possibility of permanence.

The present program of the Shipping Board is to build as many wooden ships as can be built, perhaps a few hundred instead of the 1,000 about which there has been so much talk in the past three months and so little performance, and steel vessels of about 3,000,000 gross tonnage. For this there would be required about 1,000,000 tons of ship plates and about 300,000 tons of structural shapes. The present output of plates of size suitable for shipbuilding is close to 150,000 tons a month, a considerable part of this being for shipbuilding already under way, which must not be disturbed, and if shipyard capacity can be found or created for the new program there will not be much plate tonnage of this description available for the ordinary consumer. As there is production at the rate of 175,000 or 200,000 tons a month of light plates, narrow plates, etc., some consumers will be able to get along by modifying their plans, building smaller tanks and more of them, and so on.

The sheet requirements of the Government are being formulated and the tonnage is to be distributed among all the mills in proportion to their capacity, at prices well under the current market. The existing scarcity of sheets may not be accentuated as much as was feared recently, as general consumption may decrease. It is reported that some of the automobile makers have already expressed a desire that their shipments be curtailed.

Pig Iron Continues Advance

While the advance in steel products appears to have come to a halt, nothing of the sort is apparent in the case of pig iron. The theory is that steel making capacity has been increasing right along, while blast furnace capacity has undergone scarcely any increase, and so the blast furnace is to become the "thin neck of the bottle" instead of the steel-making department. If so, there is no occasion for billets to sell at $90 to $100 and pig iron at $40 to $50. If there is not enough pig iron to keep all the steel-making capacity in operation, the steel works will pay for pig iron the market price of steel, less the cost of conversion, rather than curtail output. Then there is the fact that scrap is scarce, the production of industrial scrap not being heavy, while with the decreased output of shell steel, with its heavy discards, the steel works are not making as much scrap as formerly.

Ten days ago Bessemer pig iron was quotable on the basis of previous sales at $45 valley furnace for ordinary lots, with small lots $46 or thereabouts. Without any sales of consequence at intermediate prices there have been sales in the past few days at $50, one lot of 10,000 tons and another lot of 9,000 tons. Basic, which had been at $42 valley, for several weeks, suddenly brought $45 in the case of purchases by one steel mill amounting to 12,000 tons, and sellers now assert no quotations are being made below $48. Foundry iron is $43 to $45 valley, and malleable $44 to $45, according to delivery, but the number of sellers is quite restricted.

HYDRO-ELECTRIC BUYS OUT ONTARIO POWER CO.

SIR ADAM BECK announced last week that the Hydro-Electric Power Comission of Ontario has acquired the assets of the Ontario Power Co. for $22,669,000 on the following terms:—

The company agrees to deliver all its Canadian properties, along with all its physical assets and contracts for the delivery of power, in return for which the commission agrees to pay in its own debentures to the extent of $8,000,000 for the $10,000,000 of stock now held by the company, and to assume the bond liability of $14,669,000 secured by a first mortgage on the property. The company is to receive the current assets and to assume the current liabilities.

The Hydro-Electric Commission will take possession of the property on the first of August. The municipalities will get their power at nine dollars per horsepower, and even selling power at that low figure it is estimated the plant would pay for itself in twenty-five years.

The principal owner of the Ontario Power Company was John Joseph Albright, of Buffalo, N.Y., who agreed to sell to the Hydro-Electric Commission ninety thousand shares of the company's stock at $80 per share. The shares have a par value of $100 each, and Mr. Albright has undertaken to accept as payment Hydro-Electric four per cent. forty-year bonds. There is now invested in Hydro property in this province practically seventy million dollars, including money put in by the municipalities.

Estimates made by the Hydro-Electric Commission's technical advisers, headed by Fred Gaby, chief engineer of the commission, show that the estimated revenue per annum from the sale of power is $2,396,277; the operating expenses, rentals, taxes, etc., will be $804,718; the fixed charges, interest on bonds, sinking fund, etc., will be $990,550; the total operating expenses, $1,795,268, leaving a balance of $601,009 for the year. From that will have to be deducted interest and sinking fund on the $8,000,000 worth of Hydro bonds, which will amount to $400,000, leaving a balance for depreciation of $201,009.

INSTRUCTIONS TO LAKE MARINERS

UNDER authority of law and of regulations prescribed by the Secretary of War to govern in case of obstructions in St. Mary's River, the following notice and instructions to mariners are issued by Lieut.-Col. Burgess, engineer officer in charge of river improvements:—

The Lighthouse Bureau has marked with two red spar buoys, carrying red lights at night, the channel bank of Pipe Island, opposite and above the wrecks of the steamers Pentecost, Mitchell, and Saxona. The wrecks lie about 1,500 feet south by west of Pipe Island light, with stacks and spars showing above water, and are marked at night by lights maintained by the owners. The available channel between the wrecks and Pipe Island bank, measured at right angles to the sailing line, has a clear width of only about five hundred feet, of which width about four hundred feet is on the easterly side and one hundred feet is on the western side of the chart vessel course. Masters are warned that vessels must not meet or pass each other in the immediate vicinity of the wrecks.

The Coastguard Service has designated the small tug Minto K. as a special patrol vessel to oversee the passage of vessels in accordance with St. Mary's River rules. The patrol tug displays by day a United States coastguard flag and by night a vertical hoist of a red light above a white light. Masters are requested to co-operate with the patrol tug in keeping the channel clear and are notified that failure to comply with signals from that vessel will be punishable by penalty prescribed by law.

COKE FUEL FOR POWER STATIONS

By T. J.

THE Highways Committee of the London County Council has placed an order for eight coke-burning mechanical stokers for use under steam boilers at the Greenwich generating station. The use of mechanical stokers for firing boilers with coke fuel has passed the experimental stage in more than one power station, but the London County Council will no doubt regard the present installation as more or less experimental so far as they are concerned. It is calculated that the first set of stokers now contemplated will, if worked to their full capacity, consume 100 tons of coke per 24 hours; and having regard to the relatively high cost of coal, as well as the relatively greater degree of efficiency attained in burning coke, every effort will no doubt be made to use the new stokers to their full capacity. The present total coal consumption at the power station has been estimated at 165,000 tons per annum, and according to a figure recently published, the present price is approximately $8 per ton. Having in mind the huge surplus of coke available in London before the war, the financial advantages which should accrue to the Council by equipping their boilers with stokers which open the door to this alternative source of fuel supply should be considerable.

From a national point of view, the advantages accruing from the policy of using coke in lieu of raw coal to the extent indicated are no less important and far-reaching in their incidence, in view of the abnormal and increasing cost of imported raw materials used in the manufacture of carburetted water gas, a commodity which however desirable and useful in normal times is now regarded as expensive from more than one point of view. Based upon the total yearly consumption which is by no means the largest of any individual power station in London, the valuable residuals which would be recovered by diverting this quantity of coal through the gas works would include 1,650 tons of sulphate of ammonia, 300 tons of high explosive material, and 1,650,000 gallons of coal tar.

SHIP SEIZED IN HARBOR

ACTING on authority of the Superior Court issued by Mr. Justice Allard, in the Practice Division, J. M. Ferguson, K.C., seized the steamship Steelton, in Montreal harbor, belonging to the Matthews Transportation Co., of Toronto, as security in the action taken by a seaman named Charles A. McCarthy against the company for damages under the Workmen's Compensation Act. The plaintiff states that in November last the mate of the ship ordered him to jump from the deck of the vessel and moor it to the St. Gabriel pier. It is alleged that no ladder or other means of descent were provided and plaintiff had to obey the order of his superior officer. In the jump of fifteen feet he was badly injured, and in his action for compensation he charges that the company is responsible for the "inexcusable fault" of their officer. Release of the ship was based on the company giving security which the Court fixed at $5,000.

METZ

AT the point where the Moselle is joined by the Seille, and makes its way to the Rhine along sundry different arms, stands the ancient city and fortress of Metz. It is capital of German Lorraine, in Imperial Province of Alsace-Lorraine, 99 miles northwest of Strassburg, and 176 miles due east of Paris. Recent events have rather discredited fortresses; but, says the *Christian Science Monitor*, as fortresses went before the war, Metz was regarded by many, as the strongest fortress in the world. It was always a place of great strategic importance. The Roman, who ever chose his strong places with a judgment which all the countries since have only confirmed, early fastened on Metz, or Mediomatica, as he called it, as one of his outpost cities. He fortified it with care, supplied it with water by means of the mighty aqueduct, the remains of which still exist, and, in the days of the emperors, threw out from it his great military roads to Toul, Langres, Lyons, Strassburg, Verdun, Rheims and Trier.

Under the Romans, Mediomatica flourished, as all great fortresses in those times were wont to flourish; but it was an outpost city, and as the Empire began to weaken, and the legions were withdrawn within an ever-narrowing circle, Metz, like many other great cities and strongholds, was submerged by the barbarian tide. In the Fifth century, Attila the Hun came against it with his hordes, and took it, and the Roman legions knew it no more. Later on it came into the possession of the Franks, and was made the capital of the Frankish Kingdom of Austrasia. Then, after the disruption of the great Frankish realm under the Carolingians, it was included in the Kingdom of Germany. From the beginning of the Thirteenth century it was a free imperial city.

In consequence, Metz grew in importance and prosperity. It was the see of a succession of famous bishops, who ranked amongst the great ecclesiastical princes of the Middle Ages; whilst it was from Metz in 1356, that the Emperor Charles IV. issued his famous Golden Bull, definitely settling the law of the imperial elections. One of the great episodes in the history of Metz is, of course, its heroic defence against the Emperor Charles V. by Francis, Duke of Guise, who held the city for France. Henry II., of France, had captured the city, largely through treachery, in 1552, and almost immediately it became necessary for him to hold it against the forces of the Emperior. Francis, Duke of Guise, the French general, defied all the efforts of the Emperor to regain possession of the city, and Metz thence onwards, until 1870, remained in French hands.

During the years which followed its capture by the French it declined steadily in importance. Its population dwindled from something like 60,000 to about 22,000. It, however, retained its character as a fortress, and, in the latter half of the Seventeenth century, that great fortress builder, Vauban, reconstructed all its works and brought them into line with the needs of the day. For the next 200 years Metz figured but little in French history, and then suddenly within a few weeks of the outbreak of the war, in 1870, as the Germans gradually completed their investment of the fortress, and Marshal Bazaine and all his men were shut up within the ring of forts, all the world found itself talking about the place. Metz was invested for fifty-four days. The Prussians simply sat down before it, as they did before Paris, and waited.

On October 14, 1870, Metz capitulated—the first time in all its long history that it had fallen before an attacking force—and Marshal Bazaine and the whole army of the Rhine surrendered to the Prussian commander-in-chief, Prince Frederick Charles. The surrender has never been fully explained. Marshal Bazaine had an effective fighting force of over 100,000 men, and the surrender was so timed that it set the Prussian army free to crush the great effort then being made to relieve Paris. In 1873, after his return from captivity in Prussia, Marshal Bazaine was court martialed for dereliction of duty, and condemned to suffer degradation and the extreme penalty. This latter penalty, however, was commuted to twenty years' seclusion. He was imprisoned in the Ile St. Marguerite, but escaped in 1874 and fled to Spain. Since 1870 Metz has been immensely strengthened, and now it ranks with Strassburg as one of the great bulwarks on the western frontier of Germany.

Enlarged Canadian Trade Intelligence Service

Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department of Trade and Commerce, Ottawa, is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.

BRAZIL—Bahia, British Consul. Rio de Janeiro, British Consul General.

CHILE — Valparaiso, British Consul General.

COLOMBIA — Bagota, British Consul General.

ECUADOR—Quito, British Consul General. Guayquil, British Consul.

EGYPT — Alexandria, British Consul General.

FRANCE—Havre, British Consul General. Marseilles, British Consul General.

INDIA—Calcutta, Director General of Commercial Intelligence.

ITALY—Genoa, British Consul General. Milan, British Consul.

MEXICO—Mexico, British Consul General.

NETHERLANDS—Amsterdam, British Consul.

PANAMA—Colon, British Consul. Panama, British Vice-Consul.

PERU—Lima, British Vice-Consul.

PORTUGAL—Lisbon, British Consul.

RUSSIA—Moscow, British Consul General. Petrograd, British Consul, Vladivostock, British Consul. Odessa, British Consul General.

SPAIN—Barcelona, British Consul General. Madrid, British Consul.

SWEDEN—Stockholm, British Consul.

SWITZERLAND—Geneva, British Consul.

URUGUAY—Monte Video, British Vice-Consul.

VENEZUELA — Caracas, British Vice-Consul.

Canadian Commercial Intelligence Service

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

CANADIAN TRADE COMMISSIONERS.

ARGENTINE REPUBLIC—B. S. Webb, Acting Canadian Trade Commissioner, Reconquista, No. 46, Buenos Aires. Cable address, Canadian.

AUSTRALIA—D. H Ross, Stock Exchange Building, Melbourne. Cable address. Canadian.

BRITISH WEST INDIES—E. H. S. Flood, Bridgetown, Barbadoes, agent also for the Bermudas and British Guiana. Cable address, Canadian.

CHINA—J. W. Ross, 13 Nanking Road, Shanghai. Cable address, Cancoma.

CUBA—A. T. Quilez, Acting Canadian Trade Commissioner, Lonja del Commerci, Apartado 1290, Havana. Cable address, Cantracom.

FRANCE—Philippe Roy, Commissioner General, 17 and 19 Boulevard des Capucines, Paris. Cable address, Stadacona.

JAPAN—E. F. Crowe, Acting Canadian Trade Commissioner, P. O. Box 109, Yokohama. Cable address, Canadian.

HOLLAND—P. H. Geleerd, Acting Canadian Trade Commissioner, Zuidblaak, 26, Rotterdam. Cable address, Watermill.

RUSSIA—C. F. Just, Canadian Government Commercial Agent, Alexandrinskaia, Plosch 9, Petrograd. L. D. Wilgress, Canadian Government Commercial Agent, Bukhgolza Ulitza No. 4, Omsk, Siberia.

NEWFOUNDLAND—W. B. Nicholson, Bank of Montreal Building, Water Street, St. John's. Cable address, Canadian.

NEW ZEALAND—W. A. Beddoe, Union Buildings, Customs Street, Auckland. Cable address, Canadian.

SOUTH AFRICA—W. J. Egan, Norwich Union Buildings, Cape Town. Cable address, Cantracom.

UNITED KINGDOM—Harrison Watson, Sub-division E.C., 2, 73 Basinghall Street, London, E.C., England. Cable address, Sleighing. London. N. D. Johnston, Sun Building. Clare Street, Bristol. Cable address, Canadian. J. E. Ray, Central House, Birmingham. Cable address, Canadian. J. Forsyth Smith, 31 North John Street, Liverpool. Cable address, Cantracom. F. A. C. Bickerdike, 4 St. Ann's Square, Manchester. Cable address, Cantracom. J. Forsyth Smith, Acting Canadian Trade Commissioner, 87 Union Street, Glasgow, Scotland. Cable address, Contracom.

CANADIAN COMMERCIAL AGENTS

AUSTRALIA—B. Millin, Royal Exchange Building, Sydney, N.S.W.

BRITISH WEST INDIES—Edgar Tripp, Port of Spain, Trinidad. Cable address, Canadian. R. H. Curry, Nassau, Bahamas.

NORWAY AND DENMARK—C. E. Sontum Grubbegd No. 4, Christiania, Norway. Cable address, Sontums.

SPAIN—J. F. Roberts, Care British Consulate General, Barcelona.

CANADIAN HIGH COMMISSIONER'S OFFICE

UNITED KINGDOM—W. L. Griffith. Secretary, 17 Victoria Street, London, S.W., England. Cable address, Dominion, London.

DOMINION STEEL CORPORATION OUTPUT

THE Dominion Steel Corporation report shows that new records were made in steel products, but that coal production was less than in recent years owing to difficulties of transportation. Steel production for two years compares as follows:

	Mar., 1917	Mar., 1916
Pig iron	346,926	329,664
Steel ingots	377,079	371,086
Bloom and billets for sale	144,051	142,252
Rails	17,495	35,197
Wire rods for sale	67,492	55,106
Bars	5,259	8,017
*Wire	35,142	36,058
Nails	20,175	19,262

*This includes wire used in manufacture of nails shown in next line.

"The distribution of shipments continues to follow the lines indicated in last year's report," comments the president. "The production of steel for munitions in the form of blanks, barbed wire, etc., has, however, advanced to the first place in importance, and preference is given to this over all other forms of steel. The next element in order of importance is the material furnished to manufacturers in Great Britain, France and Canada, engaged in the production of war materials, for which a strong demand still continues."

The total production of all the collieries was considerably below that of recent years, amounting to 4,279,772 tons, against 5,261,198 in 1916, 4,550,512 in 1915, 5,047,683 in 1914, and 5,051,603 in 1913. "The causes of this falling off," says Mr. Workman, "were beyond the control of your directors, arising for the most part from the scarcity of men consequent upon enlistment for service overseas, and also to a considerable extent from the lack of adequate transportation facilities."

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

ENGINEERING

Bracebridge, Ont. — The Muskoka Foundry Co., contemplate making an extension to their plant.

New Westminster, B.C.—A builder permit has been issued to the Westminster Mill Co., for the construction of a frame boiler house, 40 by 60, at an estimated cost of $1,000.

Brantford, Ont.—The Brantford Computing Scale Co., have purchased a site to the rear of their factory. It is understood that extensive additions will be made, including a foundry.

Port Coquitlam, B.C.—A. F. Bernstein of Vancouver, is negotiating with the City Council over a proposition to establish a smelter and steel works here. It is understood that the plant would cost $500,000.

St. Catherines, Ont.—The St. Catherines Brass Co. are going to enlarge their plant at a cost of $15,000 and will be exempt from taxes for ten years. This firm will manufacture plumbers supplies and brass fittings.

Peterborough, Ont.—A big transformer built for the Ontario Hydro-Electric Commission burst into flames about four o'clock Sunday morning in the transformer test department of the Canadian General Electric Co., and was seriously damaged by fire and water. E. G. Patterson, general superintendent of the plant, estimated the loss at $10,000.

Winnipeg, Man.—The steel of the old Louise Bridge, weighing some 20,000 tons, and now housed in the city yards is to be sold by tender together with all the scrap and other old metal that can be scraped up by the various civic departments. Controller Cockburn told the Board that present opportunities of disposing of old metal would never be more favorable.

ELECTRICAL

Kingston.—The civic utilities commission was notified by the Hydro Electric Commission that hydro will be connected with this city by August 15.

Petrolea, Ont.—The Town Council has passed a by-law authorizing the issuing of 20-year debentures to the amount of $15,000, to enable the Petrolea Hydro-Electric Commission to make extensions of the power line to various industries and pumping outfits that are asking for power.

Hamilton, Ont.—Manager Sifton, of the Hamilton Hydro Commission, has recommended to the Hydro-Electric Board that a $12,000 electric plant be installed upon the premises of the Dominion Steel Foundry. He said that company was now demanding 600 or 700 additional horse-power, and that the installation of a sub-station at that plant would defer the construction of the contemplated substation on Trolley Street about two years. The latter would cost $35,000, he declared. The board will consider the proposition.

MUNICIPAL

Tilbury, Ont.—The Town Council contemplate installing a pumping plant. Engineer, J. J. Newman, Windsor, Ont.

Montreal, Que.—P. E. Mercier, city engineer, and Controller C. Cote, favor installing a garbage destructor plant to cost $1,000,000.

St. Thomas, Ont.—The St. Thomas Packing Co. will have to vacate their property to make way for a sewage disposal plant.

St. Mary's, Ont.—The Town Council will likely expend $1,500 for the purchase of a small motor-driven pump for the pumping plant.

Hamilton, Ont.—The Provincial Board of Health has granted the city's application in regard to waterworks extensions. An expenditure of $127,000 on new pumps at the Beach station is now authorized without reference to the ratepayers.

Toronto, Ont.—The York Township Council passed a by-law authorizing the Clerk to take preliminary proceedings for the construction of a 6-inch water main to supply residents at Baby Point crescent, between Langmuir avenue and Talbot Place.

Belleville, Ont.—By-laws to equalize the assessment of all local manufacturing establishments and to purchase Victoria Park for $5,000 were carried by the ratepayers. The first named had a majority of 35 over the required two-thirds, and the park by-law had a majority of 277.

St. Johns, Nfld.—The Newfoundland Shipbuilding Co., whose agent Messrs. Amonsen & Strong, have been here selecting a site the past month will likely decide on Harbor Grace as the most suitable locally for their operations. The principal in the undertaking is Christopher Hannevig, of Christiania Norway, whose headquarters are at New York.

Victoria, B. C.—The Coughlan Shipyards of Vancouver have just laid the keel of the second of the fleet of six steel steamers being built by them for the Imperial Government. This vessel will be launched in December and will be ready for delivery early in the new year.

Peterborough, Ont.—The bridges bylaw passed by a large majority on May 31. The purpose of the by-law is to enable the Council to construct a high-level bridge over the River Otonabee for vehicular, foot and street railway traffic on Hunter Street, at the estimated cost of $260,000, and also to construct a bridge for vehicular and foot traffic at London Street across the River Otonabee at an estimated cost of $20,000. The bridges by-law was an important factor in the re-establishment in Peterboro of the Quaker Oats plant, which was destroyed by fire in December last. The company has already commenced the erection of a new plant, the cost of which will exceed $1,000,000.

GENERAL

Goderich, Ont.—The North American Chemical Co., propose building an addition to their factory to cost about $25,000.

St. Catherines, Ont.—The St. Catherines Silk Mills contemplate building a factory at the corner of Page and Queen Streets. The cost is estimated at $60,000.

Quebec, Que.—Fire on June, 1, destroyed the plants of the Frazerville Chair Co., at Frazerville, county of Temiscouata. The loss is estimated at $30,000, partly covered by insurance.

St. Catherines, Ont. — The Bonner-Heddle Co., who have a factory at Paris, Ont., propose to build within six months on their property back of Vine street. The building is to cost not less than $30,000. This firm will handle and treat foreign and domestic wool or known as carbonizing wool process.

Gravenhurst, Ont. — The Canadian Potash Corporation have about closed negotiations with the Gravenhurst Stone Crushing Co., to lease their large plant and immediately commence the manufacture of potash. It is stated that considerable percentage of potash exists in the Felspar veins in Muskoka granite and a large deposit is available right at the mill,

CONTRACTS

Hamilton, Ont.—The Canadian General Electric Co.'s tender of $1,420 for switchboard extensions has been accepted by the Hamilton Hydro-Electric Commission.

Toronto, Ont.—The John V. Gray Construction Co., Toronto, have been awarded a contract for the erection of a box storage building for the Swift Canadian Co., on St. Clair Ave., Toronto.

Toronto, Ont.—At a meeting of the York Township Council, the Ritchie Construction Co. were awarded the contract for the construction of a concrete road bridge on Finch avenue, at $4,562. The contract for the construction of a culvert on Eglinton avenue, east of Fairbank, was awarded to A. Johnston, for $900.

ILLINOIS *Special* CUTTERS

IT has been our privilege to assist many of the largest manufacturers in the country in solving intricate milling problems by supplying Cutters specially designed to meet their individual requirements. This service is under the direction of experienced engineers who design all special tools and supervise their manufacture from the selection of the high speed steel to the final testing of the finished product.

If you are confronted with difficult milling or hobbing problems, it will pay you to get in touch with us.

ILLINOIS TOOL WORKS, CHICAGO, U.S.A.

Canadian Representative: ALLAN B. WEARING, Canadian Pacific R.R. Bldg., Toronto, Ontario

Brantford, Ont.—A contract has been let to the General Supply Co., for three Electro-Bleaching-Gas. Co. liquid chorinators.

TENDERS

Swift Current, Sask.—Tenders will be received until June 19, by the City of Swift Current, for one Motor-Driven Centrifugal Pump having a capacity of 800 Imperial gallons per minute against a 300 ft. head. Geo. D. Arnott, City Clerk.

Trail, B.C.—Tenders will be received up to June 13, for work in connection with the extension of the waterworks system. Plans and specifications may be seen at office of W. E. B. Monypenny, city clerk, or at office of A. L. McCulloch, consulting engineer, Nelson, B.C.

Stratford, Ont.—Tenders will be received up to June 11, for furnishing and constructing a radial brick or concrete chimney and foundation for the refuse incinerating plant on St. Patrick Street, Stratford. Specifications and forms of tender may be obtained from the office of the city engineer, A. B. Manson.

PERSONAL

George Bury, vice-president of the C. P. R. is on his way to the west on his annual inspection trip.

L. C. Fritch, who has been general manager of the CanadianNorthern Railway, for four years, and who came to the road from the Chicago and Great Western Railway has been appointed general manager of the Seaboard Air Line.

Sir William D. Reid, president of the Reid-Newfoundland Railway, and **J. K. L. Ross**, a director of the C.P.R., have been elected directors of Dominion Steel Corporation to fill vacancies caused by the death of the Hon. Robert Mackay and Hon. David Mackeen.

B. M. W. Hanson, vice-president and works manager of the Pratt & Whitney Co., Hartford, Conn., and Dundas, Ont., has been appointed chairman of a subcommittee of the general munitions board on machine guns by the council of national defense in Washington.

H. .R Charlton Honored.—The International Jury of the Panama-Pacific Exposition announces that an award of a gold medal and diploma has been made to H. R. Charlton, General Advertising Agent of the Grand Trunk Railway System, for his work as collaborator. The Grand Trunk Pavilion and exhibit at San Francisco were among the features of the big fair.

Sir Joseph Wesley Flavelle, Bart., Chairman of the Imperial Munitions Board, has been included in the King's birthday honors, having been created a Baronet in recognition of his services to the State in the above capacity. Sir Joseph is president of the William Davies Co. and the National Trust Co. He was born near Peterborough in 1858, and his home is in Toronto.

David E. Park, one of the most prominent steel manufacturers in the United States, died at Pittsburg, Pa., on May 30, at the age of 68 years. Mr. Park was one of the organizers of the Crucible Steel Company and formed the Park Steel Company, a $10,000,000 concern, which was later taken over by the Crucible Company. He also built Pittsburgh's first "skyscraper."

A. G. Norris, transmission expert, with the S K F Ball Bearing Co., Hartford, Conn., will spend about three months in Canada on behalf of this concern and in co-operation with the Canadian Fairbanks-Morse Co., who are the sole agents for Canada for the S K F transmissions. Mr. Norris will work on transmissions only and divide his time between the Montreal and Toronto territories.

James Pender, for the past twenty-five years managing director of James Pender & Co., St. John, N.B., nail and wire manufacturers, died on May 30. The late James Pender had a long connection with the trade, having commenced his business career fifty-one years ago as a clerk with T. McAvity & Sons, hardware merchants of St. John. He subsequently commenced the manufacture of horseshoe nails on his own account and later took W. O. Purdy into partnership under the present firm name. The manufacture of wire nails was added, and Mr. Pender was made managing director of the firm. He was a member of the St. John Board of Trade, and was recognized as one of the most prominent manufacturers in the district.

James Spelman, president of the John S. Metcalf Co., grain elevator engineers and builders of Montreal, London, Chicago and Melbourne, died at his home, on Cote St. Antoine Road, Westmount, Que., on May 27. He was born at Ottawa, Ont., December 10, 1860, was educated in the Ottawa Schools and was graduated from the Royal Military College, Kingston. He was employed for some time on C.P.R. construction work in the West and later went into grain elevator building, being associated with the Metcalf Company for twenty years. He was president for the past five years. He was a member of the Engineers' Club, the Canadian Society of Civil Engineers and the Western Society of Engineers.

INCORPORATIONS

Rein Drive Tractors, Ltd., has been incorporated at Ottawa with a capital of $5,000,000 to acquire as a going concern Canadian Rein Drive, Ltd., Toronto, Etc. The incorporators are Harry M. Tandy, J. W. F. Kerr and W. A. MacFarlane all of Toronto.

Kinleith Paper Mills, Ltd., has been incorporated at Ottawa with a capital of $400,000 to manufacture paper and pulp at St. Catherines, Ont. The incorporators are William Bain, Robert Gowans and T. H. Simmonds all of Toronto.

Kilcon Knitting Mills of Canada, Ltd., has been incorporated at Ottawa with a capital of $50,000 to manufacture hosiery and knit goods of all kinds at

Three Rivers, Que. The incorporators are J. W. Blair, F. T. Laverty and C. A. Hale all of Montreal.

Guelph Carpet & Worsted Spinning Mill, Ltd., has been incorporated at Ottawa with a capital of $40,000 to manufacture rugs and carpets, etc., at Guelph, Ont. The incorporators are Robert Dodds, Roland Dodds and George McPherson all of Guelph, Ont.

The Liquid Carbonic Co., has been incorporated at Ottawa wit ha capital of $10,000 to manufacture and deal in chemicals and gases of all kinds. The head office is at Toronto and the incorporators are W. A. J. Case, J. B. Taylor and W. M. Smith all of Toronto.

MARINE

Less New York Shipping.—Twenty-one ships less in April arrived at the port of New York in May. There were 428 arrivals with a total tonnage of 1,099,433, as compared with 449 ships with a total tonnage of 1,149,740 for the month of April.

Forty-five more ships sailed from New York, however, during May, with a total tonnage of 1,155,508, as compared with 383 vessels of 1,043,466 tons for the previous month.

American vessels arriving during May number 127, six more than April, while 134 American ships left port, as against 107 vessels of American registry during April.

The principal departures for May, besides American were: British, 136; French, 11; Scandinavian, 77, and Dutch, 24, as compared with British, 140; Dutch, 17; French, 9, and Scandinavian, 71, for April.

Among the ships of all other nationalities which arrived here last month were: British, 144; French, 12; Scandinavian, 94; and Dutch, 12; as compared with, British, 141; French, 12; Dutch, 24, and Scandinavian, 104, for the month of April.

Victoria, B.C.—Despite rumors to the contrary, Mr. Butcher and Capt. Troup representing the Imperial Munitions Board, have placed no orders for wooden ships. They are conducting an investigation as to the possibility of developing the industry on the Coast.

New Westminster, B. C.—J. C. Shields and Capt. Robinson, ex-mayor of Kamloops, who are at the head of the Pacific Shipbuilding Co., a concern recently organized to build wooden steamers on the Fraser River, are making arrangements for the location of their plant on the south side of the river just above the bridge.

Halifax, N.S.—Mr. McGillivray, president shipbuilding commission, addressing the Board of Trade recently, stated that representatives of large steel shipbuilding interests had recently visited the city and were to return with some definite proposition and the city should be prepared to state what it was willing to do to assist in the establishment of a large enterprise.

New Lakes Vessel Puts to Sea.—Under

command of Captain Perry, of Cherbourg, France, and manned by a crew of Frenchmen and Chilians, the steamer Toulouse, just completed at the Superior Shipbuilding Co.'s yards, cleared from Duluth, Minn., on June 3, for the Atlantic, where she will be used in coasting and in the North Sea trade. The boat is 254 feet long, 48 feet beam and 24 feet deep and is built along ocean lines, with deckhouse amidships. The Orleans Railway of France is her owner.

Will Omit Canadian Calls.—The White Stare Line, acording to the local agent at Port Huron, Mich., has decided to omit all landings at Canadian ports hereafter, and will confine the trips of its boats to the American side. This action has been brought about by the recent announcement that the Government will in future enforce the ruling of the Department of Commerce and Labor that all passenger steamers carrying freight instal a sprinkling system for fire protection.

Big Shipping Profits.—The report of the Oceanic Navigation Co., White Star, for last year, shows a profit of £2,402,758 after providing for excess profits taxation. The profit represents an increase of £434,473 over 1915, which is more than double that of 1914. Dividends of £750,000, equivalent to 20 per cent., have been paid, leaving a balance of £300,636 to be carried forward, compared with £156,768 in 1915. Dividends of 35 and 30 per cent. were paid in the previous year. Last August the capital of the company was increased by £750,000; £375,000 of the White Star consists of 33 vessels and the capital of the company is owned by the International Mercantile Marine.

Reid Wrecking Co. Sold.—The business of the Reid Wrecking Co., with its fleet of tugs and wrecking apparatus, has been sold to the Reid Towing & Wrecking Co., a corporation headed by Roy Wolvin, of Duluth, according to a statement given out on June 1, by Captain J. T. Reid. Mr. Reid and his brother, Wm. H. Reid, are associated with the new company. It is expected that J. T. Reid will be manager. The Reid drydock at Port Huron is not included in the transaction, but will continue under the present management. The tugs transferred are the S. M. Fischer, James Reid, Sarnia City, Smith, Diver and Manistique. It is probable that the Port Huron and Sarnia offices will be continued as at present.

Tusket, N.S.—The Tusket Shipbuilding Co., Tusket, N.S., expect to lay the keel of their first ship some time in July, as the moulds are being made and the company's timberman is now at work acquiring timber. It is intended to build 4-masters of about 500 or 600 tons, with auxiliary engine space. The vessels will be standardized as far as possible to facilitate and expedite construction. Robie McLeod of Liverpool, N.S., who has built some 70 wood sailing craft during the past 30 years will be master shipbuilder. It is proposed to have two shifts at work in the period from dawn to dusk, in which case from 30 to 40 hands will be employed. All communications relating to the enterprise shouid meantime be addressed to Louis N. Fuller, 163 Hollis Street, Halifax, N.S.

Steam Barge Burned.—The steam barge Sand King, owned by W. Fraser, of Montreal, and in charge of H. F. Cumming, of Cornwall, was badly damaged in the St. Regis river near the Indian village of St. Regis, on the morning of June 1, by a fire which broke out near the boiler room. The Sand King was anchored in the river the night previous, preparatory to commencing loading operations the following morning. On the boat, besides Mr. Cumming, were Louis Hence, of Summertown, the mate, and Frank Garvin, of Farran's Point, engineer. The cabin and sleeping quarters, cooking utensils, shovels, and everything about the deck, were completely destroyed. The boat was beached in five feet of water, which saved the greater part of the hull. The loss is partially covered by insurance. Mr. Hence had his hands badly burned and Mr. Cumming also had one hand slightly burned.

TRADE GOSSIP

The Canadian Fairbanks-Morse Co., Montreal, have subscribed $3,000 towards the Y.M.C.A. Overseas Fund.

Big Locomotive Order.—It is reported in New York financial circles that Russia has placed an order with American manufacturers for 500 locomotives to cost approxmately $25,000,000, and 10,000 cars at $15,000,000. Contracts have not yet been signed, but all preliminary arrangements, it is understood, have been completed. This is said to be the largest single order for raildoad equipment received in this country.

Customs Revenue for May.—The Dominion customs revenue for May amounted to $17,144,368, the largest monthly return in the history of the country. The revenue increased by $4,089,987, as compared with the corresponding month last year. For the two months of the fiscal year which have now elapsed the total customs revenue was $31,293,525, as compared with $23,400,953 for the corresponding period during the past fiscal year.

Smoking Prohibited Where Explosives Are.—An Order-in-Council has been passed at Ottawa prohibiting persons employed on docks, vessels, vehicles or in stores where ammuniton, explosives or inflammable substance required for the manufacture of explosives are stored from smoking or having any smoking materials in their possession while in the vicinity of such places. Persons in a state of intoxication are forbidden to enter the places mentioned. A fine of $5,000 or imprisonment for five years, or both, may be imposed for contravention of the order.

Copper Output Expands.—The four leading porphry copper companies, Utah, Ray Consolidated and Chino, produced 38,230,302 pounds of the metal in April, an increase of 1,645,267 pounds over March. The natural deduction to be made from these figures is that improved weather conditions marked the April operations, while labor was probably in better supply. Utah's output increased 1,718,836 pounds over March and 2,674,230 pounds over April, 1916. Chino beat its March total by 168,023 pounds and surpassed April last year by 1,872,604 pounds. The others fell behind March slightly, but Ray Consolidated topped the total of April, 1916, by 608,491 pounds. Together the companies exceeded the production of the preceding April by 5,166,616 pounds.

The Canada Cement Co., is understood to be turning out at Longue Pointe, Que., about 50 tons a day of high-grade low phosphorous iron, which is selling to-day at a phenomenal price, about $70 to $75 a ton. With the shell orders nearly completed the management decided some time ago to make use of the electric process and take some advantage of the existing great scarcity of pig iron.

New Type of Tractor to Haul Guns.—A Washington, D.C., despatch states that a new type of tractor combining power, speed and ability to turn within its own length, has been developed by army engineers for hauling guns of medium calibre. It is believed the tractor will result in the elimination of artillery horses almost entirely. "The new creeping or self track laying type of small or medium size developed by the American army," says the announcement, "is built without steering arrangement in front, and while possessing relatively as much power as the type now used in France, is capable of turning within its own length by simply reversing or stopping one of the creeper drivers while the other side continues to move." Eventually, it is believed, horses will be used only for the lightest artillery required to move rapidly over bad ground.

Montreal and Lachine Ry. Anniversary.—Wednesday, May 30th was the 60th Anniversary of the Montreal and Lachine Railway Co., opened in 1847, and which the Grand Trunk, when that newly formed company came on the scene, in 1852, took over, as it took over other small pieces of road, in those far-off pioneer days. It was the first railway in the country, on this side of the St. Lawrence; but there was in 1836 a bit of line called the Champlain and St. Lawrence Railway and which operated more or less erratically between Laprairie on the South Shore and St. Johns—a line whose ultimate objective, between rail and boat, was Kingston, via Prescott. In the building of the Montreal and Lachine Railway, an engine disappeared in the "bog" as the district traversed might be called and was never heard of afterwards. The anniversary has an interest for railway people, and for others, too, for that was the beginning of railway life and activity in the country—new and undeveloped, and which was opened up by the Grand Trunk which now serves the most populous portions of the Dominion in Quebec and Ontario.

Will Roll Steel Rails.—Owing to the urgent need of the Canadian railroads for steel rails, it is announced that the Imperial Munitions Board has decided to release 25,000 tons of stel which will be manufactured into rails at the Soo plant and so cover immediate needs in this connection. It is understood that 15,000 tons will be supplied by the Algoma Steel Corporation, to the C.P.R., G.T.R. and T. & N. O. railways, while the Dominion Steel Corporation will supply their portion 10,000 tons, to the Intercolonial Railway. The former company will be occupied on the manufacture of these rails for about two weeks, and the latter company about ten days. These concerns are practically the only two Canadian companies which have rail plants ready for use, although for some long time past these works have been making shell steel for the Munitions Board. Following the completion of the above orders, it is stated that the plants will be turned back to the munitions business.

Steel for Shipbuilding.—In the United States steel trade the time is believed not far distant when the public will realize that tremendous sources are being centred on the output of material for ships. The Sparrow's Point plant of the Bethlehem organization is understood to be concentrating on ship steel to the exclusion of much structural goods. Its own shipyard will absorb a great deal of the supplies fabricated on the spot, but it is probable that other yards will draw upon the product of the mills, too. Three million tons of shipping included in the Shipping Board's plan will require approximately 1,000,000 tons of plates, shapes, etc. In view of the fact that the country's capacity for rolling and fabricating steel is in the neighborhood of 35,000,000 tons per year, the Government program would require no more than five or six weeks for the steel to be produced if all factors were co-ordinated on the task. This is from the theoretical point of view. The full capacity of the plants naturally could not be completely centred upon the task, for the steel trade as a whole would be badly disorganized. But steel makers, it is known, are speeding up the output of Government ship material, and deliveries are looked for as rapidly as the ship-builders can handle the steel.

B.C. to Supply Machinery for Wooden Ships.—At the meeting of the B. C. Metal Trades Association held recently in the offices of the association in the Pacific Building for the purpose of meeting Messrs. Butchert and Troup, who are representing the Munitions Board in connection with the placing of orders for wooden steamers, Capt Troup explained the proposed programme of the board and what machinery and equipment would be installed in the vessels. G. G. Bushby, manager of B. C. Marine, Limited, and Knox Walkem, president of the Vancouver Machinery Depot, addressed the two representatives of the Munitions Board and pointed out to them that the association represented 95 per cent. of the engineering and machinery plants of British Columbia and that the present plants could build the engines and machinery required for the vessels and if the necessary raw materials could be provided, the boilers also. Mr. Butchert stated that all orders for machinery and engineering work would be placed locally, provided the work could be handled. The policy as outlined by Messrs. Butchert and Troup was heartily approved by the meeting and a committee consisting of Messrs. G. Giles, Vancouver Engineering Works; H. Schaake of the Schaake Company and W. T. Fraser of the Vancouver Machinery Depot with Mr. Bushby as an ex-officio member, was appointed to co-operate with the representatives of the board and to assist them in procuring the machinery and equipment required for the vessels.

Will Fight Pine Blister Desease.—The white pine of Canada is valued roughly at $200,000,000. At the recent annual meetings of the Commission of Conservation, Canadian Forestry Association, Canadian Society of Forest Engineers and Canadian Lumbermen's Association, urgent resolutions were adopted favoring the appropriation by the Dominion Government of $50,000, to provide for supplementing the work which will be done by the Provinces of Ontario and Quebec in locating and eradicating the pine blister disease, and for making a general survey of the situation throughout Canada. Scouting is necessary in New Brunswick and Nova Scotia to determine whether the disease has yet become established in those Provinces; and attention must also be given the forests of western white pine in southern British Columbia.

CATALOGUES

Vaughan Flow Meter.—A bulletin issued by the Spray Engineering Co., Boston, Mass., illustrating and describing the Vaughan flow meter which is a simple and efficient instrument for indicating the flow of liquids in pipes.

Shop Furniture.—The New Britain Machine Co., New Britain, Conn., have issued a binder contract containing a number of bulletins and price list dealing with an interesting line of steel shop furniture. The product consists principally of shop stools, racks, bench legs, portable work stands, vise stands, tote boxes, etc. Each type is illustrated and fully described, together with specifications giving the principal dimensions, etc. Other lines illustrated and described include buffing and polishing machines, lathe racks and machine guards, etc. The binder is substantial and of attractive appearance.

Progress in Water Works Pumps is the title of a catalogue issued by the De Laval Steam Turbine Co., Trenton, N.S., and compiled from the company's records. The catalogue contains a great deal of interesting information relative to development and advantages of steam turbine driven centrifugal pumps for city water supply covering the chief requirements for such installations and the suitability of these pumps for this class of work. An interesting feature of the catalogue consists of a number of brief descriptions of important municipal installations in Canada and the United States, together with half-tones showing the layout of each plant. Copies of this catalogue may be obtained on application from the Turbine Equipment Co., Toronto, Ontario.

Commercial Gear Cutting.—This is the fifth edition, revised and enlarged, of a treatise on commercial gear cutting and dealing more particularly with the commercial production of spur, helical and internal gears. The booklet has been compiled and issued by the Fellows Gear Shaper Co. of Springfield, Vt. The book deals almost exclusively with the gear shaper method of cutting gears, although for the sake of comparison brief reference is made to the formed cutter process and hobbing process. The book contains ten chapters dealing with various phases of the subject and includes principally descriptions covering the method of operating a gear shaper cutter, generating a cutter and the generated cutter at work. There are also full descriptions of the No. 6 "Fellows" gear shaper, the No. 65 helical gear shaper and other different sizes of gear shapers. The concluding chapter deals with the application of the gear shaper to other work than gears and shows a number of examples of work cut on the gear shaper. The information in this chapter will be of value to manufacturers in general. This is an interesting publication containing considerable information of value for cutting gears. There are 64 excellent illustrations, while the catalog contains 94 pages and is gotten up in an attractive manner.

BOOK REVIEW

The Embrittling Action of Sodium Hydroxide on Soft Steel.—In certain districts where feed water for boilers contains sodium hydroxide many boiler troubles have appeared which have given no little concern to boiler users and makers. Such water is found in the central Eastern part of Illinois, in the Fox River valley in the northern part of the same state, and in portions of other states. The Engineering Experiment Station of the University of Illinois has just completed an investigation of this source of boiler distress, and the results are published in bulletin 94 by S. W. Parr. It was noted that boilers using feed water containing sodium hydroxide often developed fine cracks radiating from rivet holes or extending from hole to hole. The experiments showed that the effect upon the metal is to cause brittleness which makes it less capable of withstanding steam pressure and temperature changes. Among the remedies suggested is the addition of a salt having properties which cause it to react with the alkali and yield a harmless product. Copies of bulletin No. 94 may be obtained gratis by addressing C. R. Richards, Director, Urbana, Ill.

Brought Her Husband.—In Saskatchewan recently, there was a political convention at which women were delegates for the first time, and on one of the hotel registers there appeared the registration, "Mrs. Alfred Smith and husband."

CLASSIFIED ADVERTISING SECTION

Rates (payable in advance): Two cents per word first insertion; one cent per word subsequent insertions. Count five words when box number is required. Each figure counts as one word. Minimum order $1.00. Display rates on application.

FOR SALE

FOR SALE — 1 HOLDEN-MORGAN BASE milling machine, 3-inch shell. Manitoba Bridge & Iron Works, Winnipeg.

FOR SALE—ONE LEWIS TYPE ENGINE built by Waterous Engine Works, 240 H.P., flywheel 73" x 18", automatic governor, a bargain. One steam pump, 4½" x 2¾" x 4". Write Box 217, Moncton, N.B. c24m

ONE—50 K.W., 220 VOLT, D.C. PEERLESS Self-oiling, Automatic Engine, with Switchboard complete. Two, 10 H.P., D.C., 220 volts motor; one 20 H.P., D.C., 220 volts motor; one feed-water heater and purifier 36" x 12'.—The American Motor Sales, Chatham, Ont. c24m

TWO NEW BOILERS, 66" x 16', FOR SALE, immediate shipment. One smoke stack, 54" x 80', also one C.G.E. generator, 62.5 K.V.A. with exciter and switchboard. Box 312, Canadian Machinery. (c24m)

ONE LATHE 16" x 4½' BACK-GEARED — Built by P. P. Silk Machine & Tool Co., Cincinnati, Ohio. One lathe 18" x 3', back-geared. Built by the Bradford Mill Co., Cincinnati, Ohio. Four Murchey collapsible dies. Capacity 1½" to 2½". Box 272. Canadian Machinery. ctmf

FOR SALE—STEEL WATER TOWER WITHout tank, 94 feet high. Will support tank holding 13,000 gallons. Cost new $1,600.00. Will sell for $400.00 f.o.b. cars. Northern Aluminum Company, Limited, Shawinigan Falls, P.Q. c22m

FOR SALE—132 PIECES VITRIFIED SEWER pipe, 15 of which have small pieces chipped off flange. Size 36 inches diameter, 30 inches long, 2¾-inch wall. Make us an offer. Northern Aluminum Company, Limited, Shawinigan Falls, P.Q. c22m

FOR SALE—TWO 16 x 6 REED PRENTICE Automatic Lathes. One Bertram Gap Lathe, 48 x 10. Four No. 10 Heavy Duty Baker Drills. One No. 2D Colburne Drill. One Heavy Duty Reliance Machine Co. Turret Lathe for inside boring of 6" shells. Canadian Blower & Forge Co., Kitchener, Ont. c24m

1—ROBB HORIZONTAL STEAM ENGINE, 10 x 12, 35 h.p. Just overhauled by makers. Price $300.00. 1—Heavy Duty Rockford Drill. Suitable for shells or heavy work. Weight of drill 3,600 lbs. Good as new. Write for specification. 1—Jones & Lamson 2 x 24 Turret Lathe, 2¼" hole in spindle, 16" swing, cone drive, collet chucks for bars up to 2" diameter. Or lathe can be fitted with standard universal chuck. Flat turret 16" diameter. Good condition. Price $400.00. 1—Warner & Swasey Turret Lathe. Round turret, diameter 8", hand cross feed for turret. Swing 14". Fairly good condition. Price $200.00. 1—Bertram 2-spindle Thread Miller. Made by makers for threading 18-pdr. shells. Now used for threading sockets. Good condition. Steel Furnishing Co., Ltd., New Glasgow, Nova Scotia. c2m

FOR SALE

THE NATIONAL MANUFACTURING COMpany, Limited, Ottawa, have the following machine tools for sale:—1 25-ft. Westinghouse Air Compressor, with Receiver; 1 20" Drill Press; 1 4-spindle 12" Drill Press, Cincinnati Pulley & Machine Co.; 1 Canadian Blower & Forge Co., 21" Drill Press; 2 Racine Power Hack Saws; 1 McKechnie Bertram Planer, 36" x 36" x 10' 0" bed; 1 Wagner Motor, 10 H.P., 2-Phase, 60 Cycles, 440 Volts, 1140 R.P.M., complete with starting base; 1 Barnes 21" Drill Press; 5 Simplex Lathes, never used; 2 Ford-Smith Grinders, suitable for 18-pdr. Shrapnel Shell; 2 Thread Millers for 18-pdr. Shrapnel, in need of repairs; 3 Shrapnel Furnaces; 1 Turret Lathe. c23m

SPECIAL MACHINERY

MANUFACTURERS—WE CAN UNDERTAKE work to any specification—munition production equipment or otherwise. Write W. H. Sumbling Machinery Co., 7 St. Mary St., Toronto.

S. VESSOT & CO., GENERAL MACHINE SHOP and Grey Iron Foundry. We can undertake at present time light machining and grey iron c astings, at reasonable prices. Address Joliette, Que. c1m

AGENCIES WANTED

AGENTS HAVING CONNECTION WITH large workshops factories in mechanical construction business and dealing in tools and tool outputs, wish to represent in France a good house manufacturing especially Lathes, Drills, Files, Vises, Tinware, Machinery, Tool Outputs, etc. Good references. Address Hoon & Barronnet, 11 Rue Bichet, Paris. c24m

One Advertiser Said To Us—

"One insertion of this ad will do"—when sending in copy for a condensed ad. This firm sends in from three to four ads a month, so they ought to know.

While two or three insertions give your proposition more chance to be considered, still this incident shows just what advertisers know this section will do for them. Use its service now—every time you need it.

BUSINESS CHANCES

FOR SALE—MACHINE SHOP AND FOUNDRY —good business location; good manufacturing district for general repairs. Near two railroads and Welland canal for transportation. Cheap electric power. Owner desires to retire. For further information write Box 314, Canadian Machinery. c22m

FOR SALE A MEDIUM-SIZED TWO-STOREY brick factory situated in the best small city in Ontario. Buildings in good condition, suitable for either metal or wood-working; shipping facilities unexcelled Two trunk lines; direct connections east, west, north and south. Educational advantages the very best. Plant will be sold at a bargain and on easy terms of payment, if desired. Apply Box 294, Canadian Machinery. c2m

SITUATIONS WANTED

HIGH-GRADE MAN, EXPERIENCED IN GENeral construction, manufacturing, machine shop work and heavy shells, is open for a good offer only. Box 315, Canadian Machinery. c25m

STEEL FOUNDRY EXECUTIVE, CANADIAN, with fifteen years' experience with most up-to-date plants in United States, seeks similar position in Canada. Thoroughly conversant with sales, operation and business management. Box 306, Canadian Machinery. c22m

PRACTICAL WORKS MANAGER AND MEchanical expert with years of experience in United States and Canada, a specialist in munition work, open for engagement. Best of references. Apply Box 304, Canadian Machinery. c4m

ELECTRICAL ENGINEER—COLLEGE GRADUate, five years' practical experience; now employed in large industrial plant, electric-driven; responsible position desired; money not sole object; recommendations. Box 305, Canadian Machinery. c26m

SITUATIONS VACANT

WANTED—TOOL MAKERS TO WORK ON munitions. Apply at once. Wallaceburg Brass & Iron Mfg. Co., Ltd., Wallaceburg, Ontario. c25m

MECHANICAL ENGINEER WANTED—FIRST-class opportunity for the right party. Must be energetic, ambitious, sober and have some knowledge of French. Apply Box 286, Canadian Machinery. tcmf

WANTED—SALESMEN TO SELL BABBITT metals on commission as side line. Good commission. Give full particulars as to firms represented and territory covered. Box 303, Canadian Machinery. c21m

WANTED — EXPERIENCED MECHANICAL draftsman, one who has had some experience on machine design and factory layout preferred. Apply, stating experience and salary desired, to the Goodyear Tire & Rubber Company of Canada, Ltd., Bowmanville, Ont. c23m

6" SHELL FOREMAN WANTED WITH SPEcial qualications to get production from shop at Peterborough, Ont., which has been running on 6" shell for eighteen months. Tooling and shop inspection separately organized. Foreman to give his whole attention to obtaining maximum production. Give full particulars in first application as to previous experience, references, and salary required, otherwise application will not be considered. Apply to Box 316, Canadian Machinery. c25m

INDEX TO ADVERTISERS

Manufacturing Aspect of Machine Shop Organization*

By F. G. Kent**

This paper seeks to set forth the fundamentals of a typical machine-shop organization. It begins with a discussion of the methods for introducing changes in the way of re-organization, has something to say about the kind of man who does the job and how he gets started; then goes on to an analysis of the organization by departments. Each department is described so as to show its importance, special duties and responsibilities, and relation to the whole.

In this paper it is my purpose to outline briefly the basic structure of an organization for a shop building the average line of machinery. I shall not touch at all on the commercial side of the organization, such as sales, advertising, financial, and purchasing, but will confine the paper entirely to the manufacturing end.

As all my experience has been with concerns in operation for some years before my becoming connected with them, I have always had the advantage of having considerable high-grade material, both in the way of men and equipment, ready at hand to work upon, which accounts for some of the ideas expressed below. While I have been associated with some very large concerns, I would rather these remarks apply to the shop employing 600 men or less, for a shop of this size, from the very nature of its growth and the volume of business transacted, has just as many, if not more, obstacles to overcome as the larger plant, and is usually in no condition financially to set aside any large sum for betterment work. For this reason it is necessary in a business of this sort to plan any forward move with the greatest care, in order that there may be sure profit in each change made, and all such changes may take place at such times as to cause no interference with getting out the regular product.

Care in Planning Developments

This, of course, means rather slow progress, which is apt to be discouraging to the man who is anxious to see things go, but, on the other hand, it has a decided advantage in the fact that the evolution is so gradual that there is very little opposition or unfavorable comment from foremen or workmen inclined to discredit innovations. This in itself is a very important factor toward any reorganization scheme, for, notwithstanding arguments to the contrary, the stability of any shop system depends very largely on wholehearted coöperation, from the chief executive clear down the line to the sweeper.

Saving Profits

Some time ago James Collins made the statement in a magazine article that "during the next few years some of the largest profits in American industry will be saved out of operation. Heretofore our profits have been made, but saving a profit is a different thing altogether." I quite agree with this, and my work for several years has proven to me that hundreds of small details are allowed to take the wrong course simply because they have always gone that way. We have all of us been too much concerned in systems of paying wages, with the object, of course, of getting more work at a lower cost. Sometimes straight piece work has been adopted, and again it might be some one of the several forms of the bonus or premium plan, and in nearly every one the feverish desire to get something started has precipitated action without proper planning, and has brought about useless waste of time and energy, and, in many cases, ill-feeling among the workmen. If for no other reason than that of harmony, let us leave the time-study and wage-payment schemes until we feel sure that we have very nearly gone the limit in stopping other leaks.

My first point is that wage payment, premium schemes, bonus arrangements, etc., should be the last point of attack rather than the first.

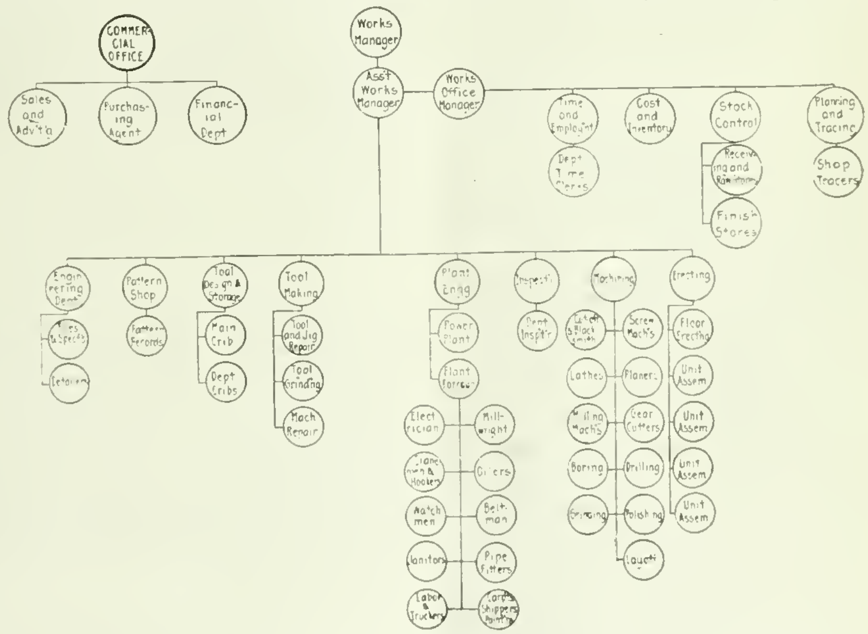

FIG. 1. PLANT ORGANIZATION CHART.

Starting-Off Reorganization

Let us suppose that we are going about the reorganization of such a shop as I have mentioned. What is the best course to take? It is my opinion that the easiest way out, and at the same time the one most profitable, is for the directors to place a man of proven executive ability at the head of a military or line type of organization, giving this man plenty of time and a free hand to work out the solution of their problems. This arrangement will prove successful more times than any other.

The selection of a title for the man who is to lead the way is a matter of considerable importance, and, if possible, the position should be a newly created one. For instance, if the chief executive has been known in the past as a supervisor or general superintendent, let the new position be that of Works Manager. Such an arrangement enables the old superintendent to retain his prestige with the men until it may be deemed proper to make a change, and it also starts the new man off with more of a punch.

The question is often asked, "Where can we get the right sort of man?"—and the answer is that he is not half so hard to find as is generally thought. Many a time the man is already in the organization, but he has been so thoroughly "hog-tied" that he has never had a chance to show what was in him.

Works Manager's Leeway

Assuming that the right man is on hand ready to take hold, if he is a newcomer in the concern he should be given at least two months to get acquainted, first with the owners, carefully analyzing their statements of trouble. After two or three days on this end of the job, let him go out into the shop and get acquainted with the department heads, encouraging them to talk of their troubles, and if possible have them express an opinion as to the causes of failures in the past. Let him drop into the works in the evenings and cultivate even the watchman's acquaintance. He will find that long hours spent alone in the shop are frequently productive of leads of value. Let him walk through the machine and erecting departments on Saturday

---

*Abstract of paper read before the American Society of Mechanical Engineers, at Cincinnati, Ohio.

**Of Lodge & Shipley Machine Tool Co.

afternoon, and an occasional Sunday for a time, looking into every corner and cubby-hole. The number of points that can be brought out in a survey of this kind will surprise one who has never tried it. All this is a mere matter of getting acquainted with the job, and it goes without saying that if this point is neglected all future work will rest on an insecure foundation.

The location of the headquarters of the new works manager should be open to all shop employees and the men encouraged to come in. It should, therefore, be in the place most accessible to the works, and it should also be perfectly plain in its appointments. The business to be transacted with the shop can be carried on over common oak desks and bare floors with a far better feeling than it can over mahogany furniture and Oriental rugs. The average workman does not care to come with his greasy shoes, soiled clothes and dirty face into an elegantly appointed office to talk about the things the manager ought to know about, and when he does, he is self-conscious and ill at ease, and goes away without half stating his case and irritated because of a feeling that he has been put at a disadvantage.

Unit Subdivision of Plant

Now, when the works manager has learned to find his way around without a guide, and the men in the shop have learned to take his presence as a matter of course, let him start the first forward move by analyzing his shop conditions and personnel, and laying down a definite organization. Of course, any organization that he may plan in the start will be changed in minor details many times, but there is no reason why the main structure should not remain practically the same as originally planned.

It is understood of course that what one is seeking for in this move is to subdivide the entire plant into a number of different units, placing a definite responsibility upon the head of each unit, and it is understood that the heads of these units will be respected in the positions they hold, or, in other words, there must be no splitting of authority or going over one's head with orders of any sort. For instance, the giving of orders directly to a workman by a general foreman or anyone else higher in authority is a serious breach of discipline, as it soon weakens the foreman's standing with the men to such an extent that he soon becomes useless as an executive. The same thing holds good, in a much greater degree, in the relationship of the owners to the head of their manufacturing operations. This may seem an insignificant point to bring out in a paper that is only touching the high spots, but I believe that many shops in need of reorganization owe 90 per cent. of their troubles to the failure to fix definite responsibility and live up to it.

This sub-division of the shop is readily visualized by means of an organization chart which will give the layout of responsibility as well as the physical layout. In making up this organization chart, I have found that the easiest way is to use round metal-bound cardboard tags distributed on a large drawing board (see Fig. 1).

The first tags made out should contain the names of the main departments. The average typical shop should have the following departments: Works Office, Engineering Department, Pattern Shop, Tool Design and Storage, Tool Making and Repair, Plant Engineering and Power, Machinery, and Erection.

This division of the shop is merely typical, and it must be understood that all sorts of variations are necessary, due to the varying factor of the personnel from which the organization has to be made. I might say here that I am a very strong believer in using the personal material at hand rather than replacing the old employee by new help.

The next step is to add to each department tag the name of the man who is selected to have charge of that department. With these tags spread out on the drawing board, with two more tags for the Works Manager and an Assistant Works Manager, and a number of smaller tags for the subdivisions of the major departments, the general shop organization begins to take shape.

I want to insert here that the Assistant Works Manager should be capable of assuming the work of the works manager in the latter's absence from the plant, and both the works manager and the assistant should have as few routine duties as possible. Their time should be spent in planning improvement and in bolstering up the weak points in the organization. A great many men get the idea that organization once done is done forever. On the contrary, the only organization that is final or complete is a dead one. I have cleaned up two plants after several firms of so-called efficiency engineers had had a shot at them. They had gone away after a time, leaving a mass of charts, forms and card indexes which were supposed to have accomplished a complete reorganization. Even if this reorganization was sufficient for the needs of these plants at the time they left, which it was not, it would be foolish to suppose that it would automatically administer affairs for an indefinite period. The business that is managed by live men is always subject to profitable changes.

Analysis of Departments

The balance of this paper can be covered by an analysis of these departments. First, the Works Office. This, to my mind, is the most important division of all; if I had to choose between a poorly equipped shop with a good works office and the best equipped shop in the world with a poor works office, I would choose the former. The head of this department should be an understudy of the assistant works manager.

The greatest fault in choosing a man for the head of the works office is getting a man who is too one-sided. Often an accountant is chosen, and he fails to appreciate the true relationship of the office to the shop; if a man of purely shop experience is chosen, he fails to understand the importance of records. He should therefore have some accounting as well as shop and engineering experience. He should have an imaginative and inventive mind to originate new forms and apply mechanical devices which insure greater accuracy and reduce the amount of labor. In this short paper it is impossible to go into details as to the possibilities of this position, but I have in mind a case where a man of this sort, through clever adaption of methods to the needs of his office, in two years' time reduced a working force from thirty-five to twenty men.

Works Office Subdivisions

The Works Office is divided into four divisions: first, Time and Employment; second, Cost and Inventory; third, Stock Control and Receiving; and fourth, Planning and Tracing.

The Time and Employment Department takes care of hiring men, application files, changes in wage rates, etc., and making up the payroll. This section also has charge of the department timekeepers maintained for the sake of accuracy of records and efficiency of foremen. The workman or foreman is never allowed to handle his own time records. In conjunction with the employment department, I have found it a benefit to the shop at large to employ a medical man and instal equipment to take care of all injuries and illness that may occur in the shop.

The Cost and Inventory Department should be able to show the cost of any job at any stage of operation, and the exact profit from the complete job. It should further be able to analyze any of the figures into direct wage, burden, material, etc., and also its records should show by comparison all previous jobs of the same sort, and, without being called upon, it should call the attention of the works manager to any unusual discrepancies in these comparisons. There should be the same type of comparison of the various accounts of indirect expenditure.

The Stock-Control Department should have charge of issuing shop orders, ordering from purchasing agent all raw material and finished material in proper quantities and in sufficient time to get the finished product on a specified date, receiving raw and finished stock, as well as storage of parts finished in the shop. Special effort must be made to secure accurate accounting of all material, as this is just as essential to the right operation of a shop as the cash balance is to a bank.

The Planning and Tracing Department establishes the order of progress of work through the shop. This department must be able to show the location of every job in the shop within a half-hour of its movement from one operation to another. It is possible to accomplish this by very simple methods. Two or three men following these records and kicking loose the dead ends, were able in one shop to lessen the number of jobs in the shop at one time from over 25,000 to less than 7,000, in addition practically eliminating the shortage of finished parts at the point of erection. When the time is ripe for time study and the establishing of standard times, this will be one of the functions of the planning department.

Engineering Department

In the Engineering Department all engineering information regarding specification has its beginning. The best arrangement is to separate the Chief Engineer who is responsible for design entirely from that section which issues the specifications to the shop. The chief engineer then has charge of the design and improvement of the product, including action on all changes suggested from any source.

The specification section takes on the work of detailing, tracing, checking, indexing, filing, making blueprints and parts lists, making bills of materials and issuing them to departments requiring them. Standard sizes should be established for all drawings and the straight numerical system identification used. For detail work one piece only should be shown on a sheet. Details should be drawn to scale, close measurements expressed in decimals and the working limits stated on each drawing. Dimensions should be so complete that the machinist does not have to do any figuring in order to find any measurement.

Assembly drawings must be furnished for each assembled unit. The assembly drawing must show the piece number of the details that go to make up the assembly, but without any dimensions of these parts being shown. I have found that showing several details on one sheet or working from dimensioned assembly drawings is bad practice. They will slow up the work in the shop and are the cause of a great deal of scrapped work.

New designs should be gone over by the chief engineer, chief draftsman, works manager and his assistant before being detailed, and the details should be criticized again before going to the planning department. It is much easier to rub out mistakes on the drawing than it is on a casting in the shop.

The Pattern Shop has the making of new patterns and the repairing of old ones, also the pattern storage and location records of patterns in the works and at the various foundries. I wish to make a point of the equipment in the pattern shop. which should be the best obtainable. There is no profit in working high-priced men on weak-kneed tools. If patterns are to be used for quantity production, ease of molding and long life should be considered in building them, but where a limited number of castings are to be made, no more time should be put on them than absolutely necessary. Lack of attention to either one of these details has caused large losses to many concerns.

Tool Design and Storage Department

The Tool Design and Storage Department takes up its work at the point where the drawings for parts to be manufactured leave the planning section of the works office. Any new jigs or fixtures required for the sake of interchangeability or economical manufacturing are designed and ordered by this department. This department is also responsible for storage, indexing and checking of jigs and smaller tools in the tool cribs in the shop, and requisitioning the purchase of small tools—taps, cutters, drills, emery wheels and so forth. The Tool-Making Department will build all new jigs and keep up repairs on old ones. The sharpening of all small tools, milling cutters and reamers must be done in this department, and under no consideration by the workman using them.

Plant Engineer

The Plant Engineer in conjunction with the power plant is an arrangement seldom found in any shop. By a plant engineer is not meant a steam or electrical engineer, but a man with mechanical-engineering training who is responsible for the physical upkeep and improvement of the plant and the use of power. The opportunity which a man in this position has for saving money and increasing output is very great. The locating of all machinery, shop furniture, line shafting, piping and wiring must pass through his hands. In one shop the writer had charge of, the load on the power plant was rapidly going beyond its capacity and steps had already been taken to install new equipment that would cost many thousands of dollars. By installing ball bearings and rearranging shafting, the plant engineer was able to reduce the load over 40 per cent. at a cost of 15 per cent. of the cost of a new power plant. There was also the saving in the cost of operation which the new power plant would have entailed.

The Plant-Foreman's Department is answerable to the plant engineer. The work that the plant engineer performs is usually taken on in a more or less slipshod manner by the heads of various other departments. He should have charge of the millwrights, oilers, belt men, pipe fitters, electricians, carpenters, crane operators, hookers, laborers, watchmen, janitors and shippers, and is responsible for the cleanliness of the plant, both inside and out.

Inspection, Machining and Erection Departments

The Inspection Department must be answerable to the works manager or his assistant only. In no case should the inspectors take instructions from any of the machine or erection-department heads. They must pass judgment on all work in process as well as the finished product. The inspection may be carried out either directly on the floor or in a centrally located inspection room. This depends more or less on the nature of the product.

The Machining Department may have one general foreman, with his assistants in charge of the subdivisions. These assistants have instructors under them whose duties comprise seeing that jobs are properly set up, tools properly selected, and proper feeds and speeds are used. There should be about one instructor for every ten men. Supervision of the machine work must be entirely separate from the erecting department.

The writer is a firm believer in placing machines of a kind together; that is, lathes in one section, drilling machines in another, and so on. It keeps down the amount of the investment. It makes a better balanced condition, and the work goes to a foreman who knows more about that particular operation than an all-round man can ever hope to know.

The possibility of improvement in the various operations of the machine shop is never-ending, and the changes in machine tools are continuous, which is a fact that the works manager and his assistant should never lose sight of. Any new tool that promises more economic production should be thoroughly tried out and, if satisfactory ,the old tool should be immediately disposed of, as it is cheaper to scrap a tool than to operate at decreased efficiency.

The Erection Department should have a general foreman, with the various units of assembly placed under his assistants, as, for instance, in a lathe shop there would be a head and tailstock department, carriage and apron department, etc., and a final erecting department of the sub-assemblies into the complete machine.

ZEEBRUGGE

ZEEBRUGGE is the seaport of Bruges, which derives its name from the fact that more than fifty bridges (Flemish "brugge") cross the many canals in and around the capital of West Flanders.

Zeebrugge is eight miles north of Bruges by rail, and six miles by way of the Canal Maritime, a modern waterway 230 feet wide, accommodating seagoing vessels with a draft of twenty-five feet. This canal terminates in the inner basin at Zeebrugge. The latter is protected from violent northwest winds by a crescent-shaped mole of concrete and masonry, a mile and a quarter in length. Crowning the land side of the mole are extensive warehouses, elevators and railway tracks. These elaborate harbor improvements were begun in 1895 and were under construction for twelve years, the cost exceeding $8,000,000.

Zeebrugge was the outgrowth of the reviving prosperity of Bruges. Before the war this one great mart of the Lowlands had begun to take on a new lease of life, with its thriving market gardens, its ceramic factory and its extensive lace works employing 6,000 hands. It would probably never have achieved the size and prosperity of its thirteenth century fame, when it is said to have had a population of 200,000, but it numbered more than 50,000 thrifty people in 1914, including a colony of nearly 3,000 English.

Zeebrugge is fifteen miles northwest of Ostend and sixty miles northwest of Brussels. One mile south of the harbor, on the road to Bruges, is an enormous old barn with great oaken beams, dating from 1280, the only relic of the once wealthy and famous abbey of Ter Doest.

APPEARANCES, GOOD AND BAD

By A. L. Haas.

THERE is a proverb which states that appearance is apt to be deceitful. Be that as it may, so long as human nature remains unchanged, externals will continue to challenge criticism and exert an influence which may or may not be beyond their real worth.

National characteristics affect the matter; certain traditions have sprung up and these have a sub-stratum of fact. Solidity and durability are apt to be overlooked, if the less important finish is absent.

First Impressions Lasting

From a commercial, no less than a human viewpoint, first sight represents a great deal. Suitability to intended purpose is a prime consideration, but attention is first attracted and the eye of a customer focused by external finish even where this is not a solid asset or is bound to disappear in use. It is commonly assumed, and the assumption is warranted by fact, that real finish is a certificate of careful work not apparent, and great pains are taken to ensure attractive externals by firms who are proud of their product.

In a human sense any individual whose looks are smart has an asset of value, though we are all familiar with the man who can obtain job after job, but fails to hold any post for more than a brief period of time. The art of making a good impression is perhaps a gift but the acquisition of sufficient manners to avoid misapprehension is not difficult. We shopmen do not need the graces of the ambassador of commerce, but this is no excuse for lack of common politeness, whether to a superior or inferior. In fact, in daily contact the power of getting willing in place of grudging assistance from above or below is dependent upon a cheerful and mannerly spirit.. In brief, it pays to be polite even to the most churlish. That tact, which avoids all cause of offence by sensing the other man's mind, is among the rarest of virtues and is a natural gift, but sufficient for daily use need involve no strenuous study.

The bird of passage who drifts from shop to shop obtains experience denied to the sticker who is in most instances the better man. The experience meant is that of interviewing prospective employers successfully. It is an art in which some men shine. From past interviews he knows very nearly what questions will be put and what answers to give. It is a most difficult thing sometimes to extract the needed facts from a really good man, who is deficient in such experience. It is like a boilermaker at home trying to explain a job to a friend —words fail—the fire shovel and a piece of French chalk say more in half a dozen lines than an hour's description.

Technicalities and Sales

From similar reasons the practical technician fails rightly to apprehend the question of sales. The more familiar he is with the details of manufacturing, the worse missionary he is likely to make in pushing their merits. It is a little curious, but none the less true, that the majority of those having the power of purchase are either non-technical or else more in a different field of effort. As a consequence, it is often those very elementary facts regarded as childish by the practical man which are required. Another matter is that the technician fails to perceive that his specialized knowledge was obtained over a term of years by slow degrees. His fault is often that he expects those totally unfamiliar with his wares to take in right away the whole of their merits.

If the advertising expert be watched, it will be seen that in place of crowding his space with all the merits and reasons, he confines his attention to one or two only. Later he uses up the other reasons singly or in pairs, varying his matter but never confusing the casual reader by making him study, or compelling him to use a magnifying glass to assort all the labels and pointers. The reasons must be sufficient, adequate and pointed, the ad must be arresting, he does not attempt to make a convert of his reader by a single explosion; on the contrary, he stimulates his interest by repetition and variation. Advertising is a matter of appearance, but of selective appearance. Salesmanship is, of necessity, of a more intimate complexion, dependent most often upon the reaction between native and nature.

No salesman may give way to exasperation, and argument is one of the worst methods of gaining an order. It is not words, lectures, speeches, or exposition which tells, but a growing conviction in the customer's mind, dependent upon the whole salesman, not necessarily upon his tongue. If the reader will cast his mind's eye backward he will realize that it is less words than quite another quality which persuaded.

Confidence a Keystone

Commerce is confidence, the entire business world hangs upon credit, upon credibility, upon faith justified by past facts.

From the retail shop to the largest manufacturing concern, the appearance cultivated is that of confidence.

The biggest advert of the lot in the appearance of the goods on delivery and subsequent satisfaction in their use. Repeat orders and the establishment of what commercially is termed good-will is worth many sacrifices in the initial stages, many things legally enforceable are suffered that relations be not disturbed. Customers who silently suffer are not friends, the man to encourage is the man who complains; it is worth spending a little time to get him pleased. Treated otherwise, he becomes often an active enemy and a missionary for a rival firm; placate him, reason with him, convince him, and another good-will link in the chain of business is established.

Mechanics and Beauty

The mechanical sections of the universe are blamed for their neglect of beauty; it is strange to the engineer to hear the artistic value of mechanical products traduced. The fact is that those who complain lack the knowledge necessary to appreciate. A power unit, a bridge, a machine, a boiler—all have artistic possibilities rightly viewed. The ancient Greeks had one word meaning both artistic and fitting and any thing correctly designed must have one merit, proportion which lies at the base of all artistic work. Art so-called concerns itself with appearance, largely with external decoration; strength and rigidity, power to resist stress are not an artist's province.

The utilitarian aspect of a machine or hardest shelled of practical men can find beauty in the products of his craft—proportion, line, and fitness find in him a qualified judge. To him such things make an instantaneous because an educated appeal. He knows and knowing can afford to smile at the criticism that he sins against art by mechanical effort. One thing certain is that the craftsman in every age has been the man upon whom the work of that age has rested, and that craftsmen of past ages would be the first to appreciate the craft of to-day.

Appearance Suggests Merits

The appearance of the finished goods has a commercial value, their design satisfies fitness to a destined end, their workmanship reveals itself by the finished look to a trained eye. Care and skill are manifest externally, near enough is not good enough. It is worth effort to attain good looks, they are a passport to favor. Moreover, that concern taking pains for appearance sake helps to cultivate a feeling of proper pride in the staff, which, insensibly and without addition raises in its turn that invaluable internal asset inside the firm-reputation. Than which it is safe to say nothing is worth more to a maker, whether his produce be implements, machines, or aught else. Reputation inside the firm and outside, along with good-will among its customers, depends in the main upon appearances which need net be deceitful after all.

A KINK IN REFITTING LATHE BOXES

By H. D.

IN fitting up half boxes for lathe headstocks it takes a good deal of time to make the brasses a perfect fit on the spindle, and at the same time have the two halves tight together. It is not considered good practice to use liners between the halves (though this is done on most all other high-class work), nor is a gap permissible. One concern that did rebuilding and turned out an average of a lathe a week followed the practice of planing the boxes off, so that when they were finally fitted (scraped) to the spindle, there was from .003 in. to .006 in. space between the halves. The face of the brasses was then tinned over, and this solder filed down until the fit desired was obtained all around. The solder filed easier and quicker than bronze, and the coating made it easier to fit up when the round part became so worn in service that refitting was necessary. No reason was ever found to condemn this method.

PASTE FOR OIL TIGHT JOINTS

By D. A. Hampson.

AN oil tight joint between metal parts which can not be conveniently packed or fused can be made by using a paste made of glycerine and litharge (oxide of lead). The powder is stirred in the glycerine until the consistency is like very heavy cream, and is preferably applied to the parts before assembling and the parts drawn together, squeezing out the paste as they are tightened up. If this cannot be done, the paste can be worked in at the edge of the joint, applying with a putty knife. It takes about two days for this mixture to harden ready for use. In one instance some sheet iron troughs, 15 feet long, were to be filled with oil and various shafts run in that oil. The ends of the troughs had to be castings set inside and held with screws. No satisfactory way of keeping these castings tight was found until the glycerine and litharge paste was used.

BABBITT METAL GIBS

By H. Middleton.

BABBITT metal makes a satisfactory gib for tables, slides, etc., when conditions can be arranged for it. During the recent call for special machines, several hundred single purpose machines were built which had a sliding table similar to that of a milling machine. The work was such that there was little strain on the gib side of the table vee and the gib merely served to always keep the table up in perfect adjustment. The sides of the vees were of the common 60 deg. bevel, and the planing of the gibs was an item worth considering.

A scheme for a babbitt gib was conceived, and looked so good that two tables were tested out—one with babbitt and the other with the usual steel gib. The saddles were clamped on the planer, side by side, with the tables in place and the tables connected to the cross rail, so they could not move—while the saddles did. The planer was run a week this way and at the end of that time an examination showed (of course) less wear from the babbitt gib, and the gib itself had worn only a few thousandths in what was the equivalent of a year's running.

So the babbitted gib was adopted and a substantial saving resulted. With this soft metal construction, a greater thickness of gib was adopted, the thickness being 11-16 in. The saddles as cast came with the gib side cored to the 60 deg. bevel, so that no planing was needed on this side, effecting a further saving. In babbitting, the table was C-clamped in place and saddle and table then turned up on edge, so that the space to be filled was most accessible. The set screws were put in and left projecting about ⅛ in. on the inside so that their pockets were cast right around them. Caps were put across the ends, and the piece was ready to be poured. Owing to the ample space, easy to pour into, no failures resulted. Old type metal was used. This makes a splendid bearing, and can be procured at an attractive price.

HANDY CHART FOR SOLVING FABRIC BELTS IN PLIES

By N. G. Near.

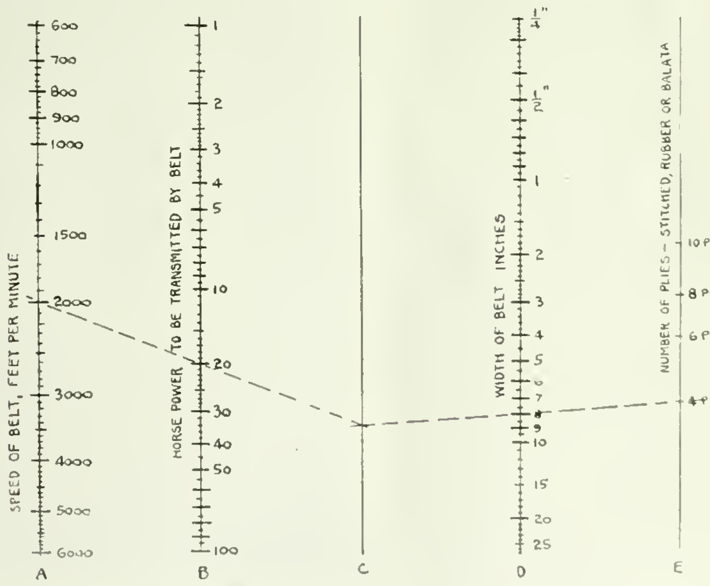
INASMUCH as charts are rare on the subject of power transmitted by fabric belts, the writer has taken it upon himself to produce something that doesn't mention the word "leather" at all. Usually we are told that a 4-ply stitched canvas belt is equivalent to a single leather belt and then we are supposed to know the rest, but we usually have to hunt around in our handbooks for formulae on leather belts, the whole thing is thus highly unsatisfactory. With this chart you simply lay a straight-edge across twice, and the answer is found without difficulty. Knowing any three of the functions—speed, power, width and ply, we can easily determine the missing one.

For example, what width of 4-ply Balata belt running at a speed of 2,000 feet per minute is necessary to transmit 20 horsepower?

Connect the 2,000 (column A) with the 20 (column B), and locate the intersection with column C, then from that point of intersection run over to the 4-ply mark (column E), and the intersection with column D will give the answer as 8 inches.

Again, if we had known the width and wanted to determine the ply, the method would have been about the same. It is so simple that I am sure any reader will understand by merely inspecting the chart.

This chart is applicable to the well known belts made up in plies such as stitched canvas, ruber and Balata, and the range, it will be noted, is wide enough to care for any ordinary condition.



HORSE-POWER WIDTH CHART FOR FABRIC BELTS

BABBITT WISDOM

By D. A. Hampson.

TO be successful in babbitting—

Avoid moisture and wear goggles.

Have the metal hot enough, but not too hot—the only right temperature is that when the babbitt will just light a pine stick—less than this is too cold to pour, more than this burns out the tin and injures the flowing and wearing qualities of the metal.

Heat more metal than you need—there will be less drop in temperature and no danger of the mould being only part filled.

Have the work as near the source of heat as possible—there is not the loss of temperature and of time and the danger of accidents with molten metal is reduced.

Don't try to use too much old lead if you "mix your own."

Make sure that the weight of babbitt is not going to break loose the caps or dams—it is always a good plan to have a helper ready to clap a bunch of waste over a dam that seems to be giving way.

Make a good big pouring hole, or more than one hole—a ¼-in. hole is the smallest that anyone should attempt to use.

Drill as many holes to vent the mould as may be needed, remembering that air and babbitt cannot occupy the same space at the same time.

Pour the metal at the highest rate possible, spilling a little if necessary to get the speed—the faster it is poured the less it will cool and the farther it will run.

Coat the shaft with graphite or oil, or even paint so it can be readily removed after pouring.

Wrap the shaft with one or more thicknesses of paper when the work is not exact, and where reamers are not obtainable—it makes the shaft a running fit without scraping—the paper can be stuck on with shellac.

Heat the casting and the shaft with a blow torch or otherwise before pouring—the babbitt will be tighter in the box and the shaft will come out easier because the relative shrinkages are less.

Build up a good high dam or riser around the pouring hole and keep this filled—there won't be so many moulds "that didn't fill up" if this is done.

Get the shaft out of the babbitt as soon as can be after the babbitt has set.

Provide ¼ in. or more of space to be filled all around the shaft.

Use genuine babbitt when the metal has to run in very thin places.

An old carpenter's plane is good to cut down an overflow of metal where the surface is broad.

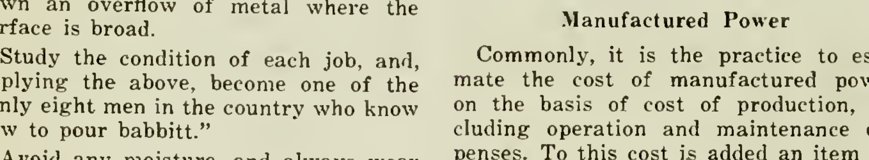
Study the condition of each job, and, applying the above, become one of the "only eight men in the country who know how to pour babbitt."

Avoid any moisture, and always wear goggles.

RASP FOR SOFT METAL

By H. Coomber.

THE rasp shown in the accompanying sketch will be found very useful in cutting down aluminum, solder and other soft metals, as it does not clog up and cuts very quickly; metal-pattern makers will find it very handy in trimming of solder on gated work. It is easily made; a file of suitable shape is softened, and then the teeth are filed to the dimensions given, a six-inch half-round file being used for this purpose. It is best to leave the rasp soft, as it keeps the edge for quite a satisfactory length of time, and can be quickly filed up sharp again.



RASP FOR SOFT METAL.

This tool is best made from three-cornered, square and half-round files; the half-round and round will be found very useful in getting around a radius. The file may be bent, if desired, about two inches from the point, which facilitates getting at sunken portions of the work.

FACTORS GOVERNING COST OF POWER*

By George P. Roux

THE important question of cost of power is one that arises daily, and in making comparative estimates of cost of manufactured and purchased power, the engineer and the business man very generally omit a number of tangible economical factors, which inadvertently excluded give little or no value to the estimated figures intended to be used—and very unfortunately often depended upon—in deciding between manufacturing power on the premises or purchasing it from a central station.

A comparison, to be of any value, must be complete, true and accurate. All the facts must be laid bare, each one analyzed, and then weighed into a scale from which the verdict will be read.

Failure to follow this process will inevitably bring to the power user costly disillusions, otherwise called "experience," with no other remedies but to suffer the loss, or to adopt corrective measures.

Of the two propositions to be considered and compared, one, the manufactured power, requires in almost every case a complicated elaboration of data to arrive at the cost; the other is more scientifically defined by a few figures for specific electrical units.

Manufactured Power

Commonly, it is the practice to estimate the cost of manufactured power on the basis of cost of production, including operation and maintenance expenses. To this cost is added an item intended to cover the fixed charges in which are included interest on the investment, insurance and taxes, depreciation and obsolescence, all estimated with various degrees of accuracy.

Other important factors are very seldom given any consideration, and more generally entirely ignored, such as floor space rental or real estate, increase in assessment of property, stand-by or reserve generating capacity and the profit productive capacity of the investment in power plant compared with the same amount of capital invested in the regular business, as well as other minor items which we propose to review in detail.

In case of an existing isolated plant there are, as a rule, more or less complete information and data which permit to arrive at a cost of production reliable only when the records have been kept accurately and properly over a period long enough to represent average normal operating conditions.

When a new plant is under consideration the task of the engineer is more complicated, and a complete knowledge of the power requirements followed by a thorough study of the situation peculiar to each case, is necessary in order to formulate an estimate of the cost of power.

After all the elements having a bearing on the cost of power, either directly or indirectly, have been carefully investigated and analyzed, and with the results in sight, the cost of power is to be determined in two parts: Cost of production, and fixed charges. To each one of these items must be charged all legitimate expenses without which the power plant could not be operated properly and continuously. The power plant should be treated as an industry within another industry, that is, all by itself.

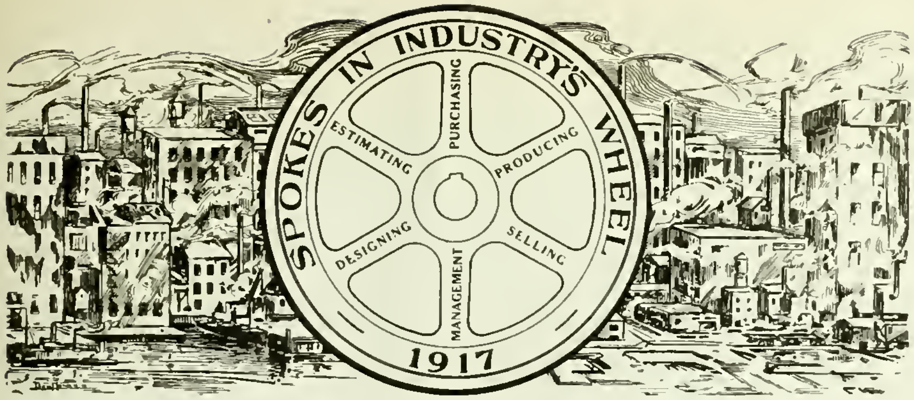
*Paper read before the Penn. Central Section, National Electric Light Association.

MISCELLANEOUS

Steel and Iron.—Reaumur discovered the direct process of making steel in 1722 or thereabouts by immersing malleable iron in a bath of cast iron. A steel manufactory is said to have been set up by Benjamin Huntsman near Sheffield in 1740. It was about 1800, however, before steel fairly became the fashion. The greatest boost to the trade came from Bessemer in 1850.

IN preparing graphite for pencil-making, it is ground very fine, mixed with water, and passed through tanks to allow the heavier particles to fall, the finer particles passing onto five or six successive tanks, when, the necessary degree of fineness having been obtained, it is mixed with suitable clay which has been washed in the same manner. The mixture is submitted to further grinding, squeezed in bags to remove superfluous water, and forced through tubes to produce strips of the required shape and sizes, which when dried and baked, are ready for casing in wood.

Sunset at 12 o'clock.—The habit of counting 12 o'clock at sunset is very ancient. The Turks, Greeks, and most other people in the Levant have almost always counted 12 o'clock from sunset and to this day the common people cannot understand that their clocks have to be changed every day and not ours. The Turks have officially adopted meridian time, but only since the Young Turks came into power—that is, since 1908. The change was even then not made immediately. It encountered a great deal of opposition on religious grounds because the Mohammedan hours of prayer are regulated by the sun. And the common people still stick to the old system. Only in Constantinople and Smyrna are there many Turks who keep the official meridian time, and the great majority of people, throughout the Turkish dominions still count 12 o'clock as their ancestors have from time immemerial, at sunset.



The constitution of industrial enterprise is largely departmental—"spokes in a wheel." This series of articles has for its object the featuring in a racy, interesting and instructive fashion, the training, experience and achievement of those who to-day are transmitting, effectively, energy in their capacity as "spokes in the wheels" of our metal-working establishments.

A. F. WHITE

"NONE but the brave deserve the fair" is a time-honored saying, with a degree of truth in it which commends itself to most people. Similarly it can with truth be said that none but the industrious deserve the reward; and, happily, it can be said with all sincerity that in Canada, more than any other country, responsibility is merited by its holders. Not only so, but instances where world-wide experience has contributed to the success of individual careers are so numerous that one is almost justified in considering the rest of the world as a training ground for Canadian industry .

The travels and adventures of A. F. White may well be an incentive, not only to young engineers who may think of their duties only as duties, but to many ambitious and erstwhile restless spirits who realize the fact that engineering careers consist of a great deal more than sitting at a drawing-board or walking around a machine shop in brass-buttoned overalls. The village of Cam, in Gloucestershire, England, was the birthplace of our "Spoke," son of a building contractor. Bereft of his father's care and guidance at the early age of three years, the future engineer's boyhood was such as to develop a spirit of self-reliance and ambition, which were later to be reflected in his varied activities and accomplishments. When aged 13½ years, with a public school education behind him and a three-year scholarship to his credit, he deliberately sacrificed the scholarship to satisfy his desire to enter the engineering trade, and despite the wishes of his mother that the scholarship should be accepted, young White "got a job" with R. A. Lister & Co., Ltd., whose works at Dursley were two miles distant from his home. Here the youthful tradesman worked for eighteen months in the erecting department, receiving wages of one dollar per week, starting work at 6.00 a.m., stopping at 6.00 p.m., and walking each way. These conditions were deliberately accepted in spite of the knowledge that the regular apprenticeship of six years could not be started until the applicant was 15 years old, this preliminary period, therefore, actually making the ultimate apprenticeship equal to 7½ years.

Agricultural engineering was the principal line of the Lister Co. at that time, and as it did not appeal particularly to our "Spoke," he became apprenticed in due course to the Dudbridge Iron Works,

A. F. WHITE.

Ltd., of Stroud, a premium being paid and agreement signed, with remuneration increasing from a dollar and a quarter per week the first year to three and a half dollars per week at the end of the term. Steam and gas engines, hydraulic and pumping machinery, etc., of high-grade design and workmanship were produced at Stroud and during four years of apprenticeship evening classes at Stroud Technical School were attended three nights per week, followed later by a post-graduate course of mechanical engineering. Outside jobs possess a peculiar fascination for apprentices, not only on account of the change from shop routine, but because of the added prestige enjoyed by the lucky youth. It was significant of Mr. White's ability that at this time he was sent out in charge of some "fair-sized propositions," and to this day he considers this to have been the best part of his training,—being thrown on one's own resources and placed in various difficult positions at an early stage.

His work in this direction received full recognition at the Paris Exhibition in 1900, when his work in erecting and fitting up the firm's exhibit of gas engines won for him a bronze medal and diploma from the authorities, a silver medal being awarded the firm.

At the age of 24, the position of assistant general foreman was reached and held for three years, followed by a year and a half in charge of the mechanical engineering department of W. G. Aston Co., London, when the position of general foreman with the old firm at Stroud was accepted. The manufacture of gas and oil engines had now been gone into almost exclusively by the Dudbridge Iron Works and experimental work formed a large part of Mr. White's duties, resulting in many improvements, two of which, the White flexible magneto and ignition lighter were used extensively for a number of years by English and French engine builders, a handsome royalty being received through his employers on account of these patents.

A special adaptability for trouble jobs and outside work resulted in Mr. White making visits to every country in Europe, much of the work being for continental governments, some of whom are now our enemies. Turkey was the scene of several visits, one job being the supervision of a semi-Diesel installation in the First Turkish Arsenal at Salonica for the the Young Turk government. A producer gas engine plant was also installed at Macri, on the Asia Minor coast, which was the first and only engine of any kind within a radius of 200 miles. The oil fields of Baku in South Russia were also visited, several large gas engines being installed here, while Algeria was also the scene of further efforts.

A desire to see the Western Hemisphere was the not unnatural outcome of this travel, and a visit to the States resulted in joining the Foos Gas Engine Co., Springfield, O., where he successfully filled the positions of draftsman, chief tester and experimenter, trouble correspondent, sales engineer and assistant chief engineer. Canada, however, as in the case of many other Britishers, was to be his ultimate destination, the Canada Foundry Co., Toronto, securing his services as chief of gas engineering department; his two years stay with this concern being featured by the design of a complete line of gas producers.

Shortly before the war started, Mr. White became general superintendent for Marsh & Henthorn, Ltd., Belleville, Ont., and like most other plant executives in this country has been actively engaged in the manufacture of munitions and the building of equipment. Numerous opportunities have arisen for the exercise of his inventive resources, resulting in a complete line of munition tools. Practically every machine at present in use on shell work by his firm has been built by them, and many of his mechanical ideas have received notice from the technical press.

Mr. White is married and has one daughter who, with her mother, shares her father's fondness for such relaxations and pastimes as motoring, fishing and boating, all of which can be enjoyed to advantage in the locality of Belleville. In the matter of religion Mr. White is Anglican, but at present is not prepared to subscribe to any particular political creed. His views on matters military are quite pronounced, however, as evidenced by his holding a commission in the 15th Argyle Light Infantry of Belleville. His advice to young men is short and concise with the full merit of personal experience behind it—"Work hard and study, stick to engineering right from the start, and read every periodical and text book available. Make up your mind, keep it made up, persevere, and success will come."

MACHINE SHOP LIGHTING

NOTWITHSTANDING individual beliefs to the contrary, most of us are creatures of habit to such an extent that we are daily guilty of gross inconsistency. A shining example of this, says the *Travellers' Standard*, is the persistence with which machine-shop owners cling to the use of local lighting units for artificial illumination. It is true that some managers are aware that a system of this kind handicaps the workmen with regard to both safety and production; yet, against their own better judgment, they often yield to the demands of the workmen for local lighting units affixed close to the working points, and in all too many cases of this kind no reflector equipment is used to protect the eyes. Wire guards are often provided to prevent lamp breakage, but these afford no protection whatever to the eyes. From this it might be almost inferred that the breakage of an inexpensnve lamp is considered more important than an injury to the workmen's eyes—organs that are irreplaceable at any price, and that are the greatest protection against accidents that mankind possesses.

Unshaded Local Lights

It is important for the machine-shop owner to realize that unshaded local lights are inefficient and harmful, and that they must be scrapped in the same way that obsolete equipment of other kinds is scrapped. Every machine shop that is equipped with a lighting system of this kind is losing money through two channels—first, through a low production rate attended by a high spoilage percentage, and second, through a high accident hazard and therefore a needlessly high accident rate. A simple experiment will illustrate the truth of these statements. Take a needle in each hand, grasping one near its eye and the other near its point, and with a strong unshaded light source (say, a 40-watt Mazda lamp) suspended 12 or 15 inches in front of the eyes, try to place the point of one needle in the eye of the other—the light source being maintained in position between the hands and the eyes, and as nearly in the line of vision as practicable. Next, interpose a piece of cardboard between the lamp and the eyes, so that the light rays are effectively screened from the eyes, and again place the point of one needle in the eye of the other. It will be found that this can be done quicker and with fewer pricks from the needle when the eyes are shaded. The same work is to be done in either case, and the greater time consumed in accomplishing it with the unscreened light illustrates the difference in the rate of production, while the greater number of needle pricks illustrates the increased accident hazard.

Specular Reflection

The evils of poorly-designed machine-shop lighting are not confined to unshaded lamps. Lighting units may be equipped with suitable reflectors, but may cause "specular reflection" on account of improper suspension height with respect to the work and the workman. "Specular reflection" is the kind of reflection that occurs at a mirror or at a polished metallic surface — the term being used to distinguish reflection of this kind from the diffuse, irregular reflection that takes place at the surface of every object that we can see. Specular reflection is particularly objectionable because it produces the same kind of effect upon the eye that is caused by placing a source of illumination immediately in front of the eye.

A person may look into a mirror, for example, and see a lighting unit behind him, in all its brightness and detail, just as well as if he were directly facing it. This kind of thing often occurs in a machine shop, particularly when work is being done on a brightly polished surface. Such surfaces act as mirrors and care must be taken with regard to the horizontal location and the vertical suspension-height of the lamps, to prevent specular reflection from the work from reaching the workman's eyes while he is in his usual working position.

A particularly annoying, yet typical, violation of this principle consists in placing a lighting unit, with a proper reflector equipment, over a milling machine, in such a position that when a fine cut is being made the bright metallic surface will reflect the light into the workman's eye. The effect is exactly the same as if the man were lying on his back and looking directly into the reflector. His vision is affected adversely and as he is quite likely to think that the remedy consists in providing a supplementary local light, he usually asks for one and often receives it—perhaps without any reflector equipment whatever. This in no sense cures the ill, but rather intensifies it, because while formerly he had one unit causing specular reflection, he will now have two, and in addition one of them will shine directly into his eyes. It is doubtful if his ability to perform his work efficiently has been increased. The chances are that it has been reduced, instead; and the likelihood of his receiving an injury has certainly been augmented.

The conditions suggested in the foregoing paragraphs are to be found in the majority of machine shops to-day, notwithstanding the fact that improved methods of illumination are at hand, and well within the means of every shop. The remedy consists in employing a lighting expert, and equipping the building with lighting units in accordance with his specifications. A competent lighting authority will see that the lighting units are installed in such a way that there will be no serious eye-irritation, either from direct rays from the lamps, or from specular reflection; and the cost of making the changes will be negligible in comparison with the benefits obtained. These benefits are commercial as well as humanitarian. For example, a workman may be enabled to centre a drill exactly, with proper illumination, in half the time required with unsuitable lighting. Moreover, he will know that the work is being done correctly, and this is something he cannot be sure of with poor lighting, except at a considerable time-expense.

Localized General Illumination

Wherever illuminating engineers have been called to study the lighting conditions of machine shops, we find that in the main they have recommended localized general illumination systems as best adapted to satisfy the conditions. A system of this kind, as applied to a machine shop, provides for an evenly distributed, well diffused illumination of medium intensity, glare and specular reflection being eliminated by the use of suitable reflector equipment and by the installation of the lighting units at a proper suspension height. In addition to this, local lighting units are installed as near to the work as may be necessary. These units are likewise properly equipped with reflectors, and are so placed with respect to the work that they fulfil their function of providing light to see by, instead of shining directly into the eyes. It should be noted, here, that while these local units are not, as a rule, rigidly secured, yet they are arranged so that the workmen cannot change the position of them to any great extent. They are not to be confused with portable lights which are necessary for certain special machine-shop operations, such as boring and reaming, and which should be handled just as any other tool in the shop—that is, a portable light should be charged against the workman who asks for it. and when returned it should be carefully examined for defects in the insulation.

The system of lighting outlined is particularly efficient as a method of varying the illumination intensity to make it suitable for different classes of work in a machine shop. The intensity required in a modern machine shop may be as low as two foot-candles for buffing, grinding, sawing, drilling, and rough bench work; three to five foot-candles may be necessary for erecting, inspecting, assembling, planing, milling, shaping, and lathe work; and a maximum of ten foot-candles is often employed for fine bench work and for drawing. If the general illumination intensity is about one foot-candle throughout the shop, it is a simple matter to select lamps and reflectors of the proper size to provide the additional intensity required for any of the foregoing classes of work. Thus we avoid that accident-creating condition of sharp shadows and contrast, which is characteristic of a shop where purely local illumination is employed. The success of a localized general system of illumination depends on proper location of the outlets, suitable suspension height of the lighting units, and non-interference with these arrangements on the part of the employees.

Lighting Maintenance

After the system is installed it is essential that it be kept at its most efficient state by proper care and maintenance. The lamps and reflectors soon become coated with oil-laden dust, or become soiled from handling. They should therefore be cleaned frequently, and in order that the expense involved may be kept at a minimum, porcelain-enameled reflectors are to be preferred. A finish of this kind does not collect dirt readily, and it is easily cleaned.

Just a word regarding the question of natural light for bench work. In continuance of a long-established practice the work-benches are almost invariably placed parallel with a wall, though there does not seem to be any sufficient reason for such an arrangement. When the benches are set close to the wall all of the workmen face the strong, natural light from the windows; and if the benches are set out from the wall a short distance so that the men can work on both sides of them, the men on the side next to the windows will cast shadows over their own work, and to some extent over the work on the opposite side of the bench as well, and then men on the other side of the benches must still face the light. There may be well-founded objections to the use of short benches placed at right angles to the walls, but so far no machinist has advanced them to us.

With such an arrangement, just as much light will fall on the working point as with the usual layout, and, moreover, a workman facing at right angles to the incoming light will be in a much better position to observe his work than one who is facing the window directly. The aisle space need not be encroached upon by disposing the benches in this way, and since the workmen are out of the passageways they are less likely to be injured by trucks or by material that is being moved about by hand. New artificial lighting units can readily be installed, or existing ones relocated to suit the changed conditions. On the whole, the suggested arrangement appears to be worth consideration.

ORDERING COMMUTATOR BRUSHES

UNLESS the style, type, size and shunt equipment of a brush can be definitely given when brushes are ordered, the following information should be furnished the brushmaker, or the manufacturer of the machine, when an order for brushes is placed:—

1—Size of brush, in the following order:—Length, width, thickness.

2—Bare or copper-coated.

3—Brush angle; also if corners are square or chamfered.

4—State whether rotation is against toe or heel of brush.

5—If to be drilled for shunts, or countersunk, or both, give full particulars.

6—If to be equipped with brush-lifting devices, give full particulars.

7—State whether for one, two or more shunts, giving length of flexibles and styles of flexible terminals.

8—Specify if shunts or brush-lifting devices, or both, are to be either attached or supplied.

9—Give all information on the nameplate of the machine.

10—Give diameter of commutator (or rings).

11—State whether or not mica is undercut.

12—Give maximum number of bars touched by the brushes.

13—Give number of segments between centre of positive and centre of negative brushes.

14—Give number of poles (or brush arms) and number of brushes per arm.

15—State if machine is of commutating-pole or non-commutating-pole type.

16—Give style or type of holder.

17—If brushes in use have not proven satisfactory, state in what respect they have failed.

18—If convenient, forward a used sample of the brushes in service. It frequently happens that a more suitable brush can be prescribed and that an examination of the original brush will not only suggest a substitute having superior characteristics, but at the same time eliminate possible errors in brush dimensions, shunt applications and brush-lifting mountings.

19—Bear in mind that brushholders differ greatly in detail and that the application of shunts for either direct or alternating-current service must be specified; otherwise the shunts might interfere with the pressure springs and a set of brushes be rendered useless.

20—It is also well to furnish a sketch of the brush.

21—If for "try-out" purposes, state what service the machine is doing; hours of service; minimum, average and maximum loads, with duration of each; also if machine is subjected to gas or acid fumes, and what, if any, troubles have been experienced.

From the above it must be concluded that if what is wanted is expected it must be made clear what is wanted. Even then it may not be available. Brush requirements are in no sense stable. It is wise, therefore, to encourage a receptive disposition and to be ready for such advances in the art as may seem worth while.

CANADIAN MANUFACTURERS' ASSOCIATION ANNUAL

THE 46th annual general meeting of the Canadian Manufacturers' Association is being held during the present week—June 12 to 14 inclusive, in the Fort Garry Hotel, Winnipeg. The official programme is as follows:—

Tuesday, June 12

10.30 a.m.—Report of secretary; report of treasurer; president's address; report of Membership Committee.

2.15 p.m.—Report of Executive Committee; report of Insurance Committee.

8.30 p.m.—Reception and smoker.

Wednesday, June 13

10.30 a.m.—Report of Legislation Committee; report of Tariff Committee.

2.30 p.m.—Report of Transportation Committee.

3.15 p.m.—Motor drive for ladies.

Thursday, June 14

10.30 a.m.—Amendments to by-laws; election of officers and committees; resolutions.

2.30 p.m.—Boat trip.

8.00 p.m.—Annual convention banquet.

The reception and smoker will be tendered visiting delegates by Winnipeg members of the Canadian Manufacturers' Association. Brief addresses of welcome will be delivered by his Worship, Mayor R. D. Waugh, of Winnipeg; Honorable T. C. Norris, Premier of Manitoba; and Mr. W. R. Ingram, chairman of the Prairie Provinces Branch. Replies will be made by Colonel Thomas Cantley, president; S. R. Parsons, first vice-president; and W. J. Bulman, second vice-president of the Canadian Manufacturers' Association. Entertainment of an informal character will follow.

The motor drive for ladies will be through the city parks to the St. Charles Country Club, where afternoon tea will be served.

The boat trip will be by S.S. 'Kenora," down the Red River, through St. Andrew's Locks, to historic Lower Fort Garry, the site of the early Selkirk settlers. This fort, the property of the Hudson Bay Company, is retained in its original state, and is leased to the Winnipeg Motor Country Club, who have kindly extended courtesies for the afternoon.

The banquet speakers will include Sir James Aikins, Lieutenant-Governer of Manitoba; W. B. Lanigan, of the Canadian Pacific Railway Co., and H. W. Wood, president of the United Farmers of Alberta. It will also be made the occasion of the inaugural address of the incoming president.

The privileges of the St. Charles Country Club, the Pine Ridge Golf Club, the Bird's Hill Golf Club, the Fort Rouge Lawn Bowling Club and the Assiniboine Lawn Bowling Club will be placed at the disposal of visiting delegates.

The Winnipeg Industrial Bureau has arranged a business men's tour through the Province of Manitoba, leaving Winnipeg on the morning of Friday, June 15, and lasting for five days.

The "Alquist" Transmission Gearing for Ship Propulsion*

By W. L. R. Emmet **

The feature of the Alquist gear that renders it specially suitable for the transmission of large amounts of power is its flexibility, which permits it to yield at points under excessive pressure. This flexibility is secured by building the gear of plates between which there is a small clearance, this clearance allowing a slight lateral movement of the periphery which relieves the stress on the helical teeth. Some results secured in ship propulsion are appended.

THE designs described in this paper are based upon the inventions of Karl Alquist, an accomplished engineer formerly connected with the Turbine Department of the English branch of the General Electric Co—the British Thomson-Houston Co. His gear inventions were first brought to the attention of the writer early in the year 1911. For some time previous Mr. Alquist had endeavored to arouse interest in his methods in England and on the Continent but had accomplished nothing. At that time the General Electric Co. had not begun the commercial manufacture of high-speed spiral gears, but had for some time been conducting experiments to determine the limits of speed, pressure, etc., which were practicable with such gearing. The importance of high-speed gearing in connection with turbine and electrical applications is obvious and the General Electric Co. was working with a view to a development of the best standards.

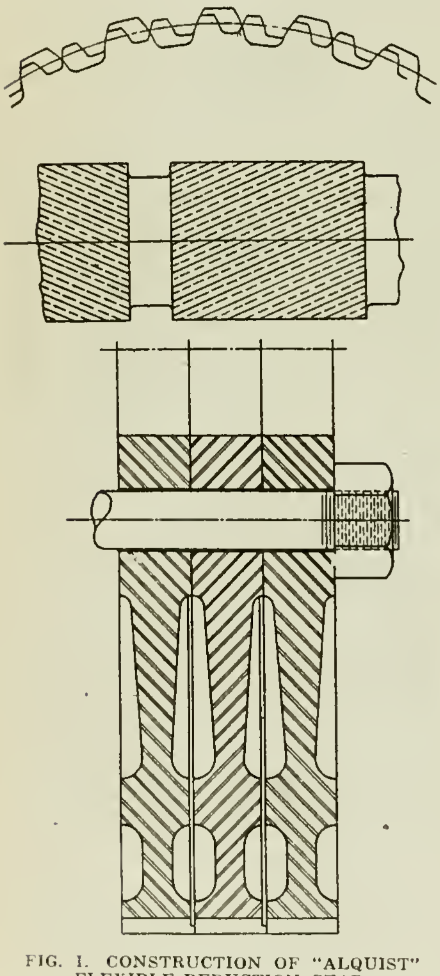


FIG. 1. CONSTRUCTION OF "ALQUIST" FLEXIBLE REDUCTION GEAR.

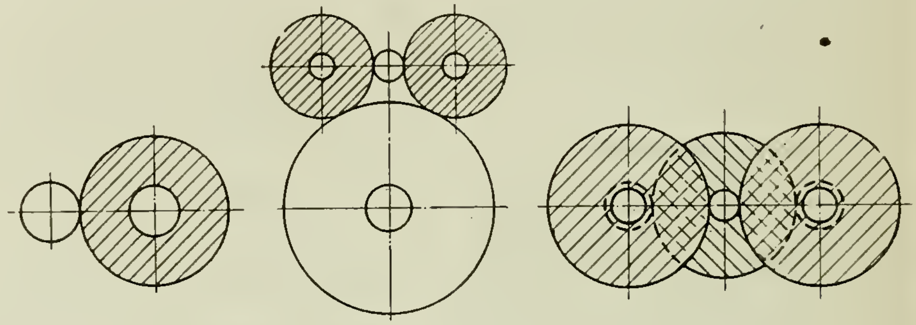

FIG. 2. VARIOUS ARRANGEMENTS OF PINIONS AND GEARS.

Certain features of Mr. Alquist's proposals appealed strongly to the writer, and arrangements were made with Mr. Alquist to come to America and assist in experimental developments along the line of his inventions.

The result of this undertaking has been that many sets of gearing have been built and experimented with exhaustively under a variety of conditions, and by these experiments certain standards of practicability have been established and extensive commercial developments have been undertaken. Gearing of this character has been applied to about seventy-two sets where steam turbines drive electric generators of various types. Contracts have been closed for machinery for the propulsion of seventy ships aggregating 215,200 horse power. Some of these electric generating sets have been in service one and one-half years and about seven of the ship sets are in service, some of them having made many long voyages. Among these are high-pressure cruising units for the battleship "Nevada" which have been in service for some time and shown very fine results. Among the ship equipments not yet completed are included the propelling machinery for Destroyer No. 69, built at Mare Island, and new propelling machinery for the scout cruiser "Salem." In all of this practical

**Consulting Engineer, General Electric Co., Schenectady, N.Y.

*From paper read before the American Society of Naval Architects.

experience no case of trouble with gearing has developed and no appreciable deterioration of gears has been observed.

One of the important reasons for adopting this type of gearing was that its design tended to afford a distribution of strains and means by which excessive strains would not be imposed upon any part through slight imperfections, distortions, or inaccuracies. The uniform success which has been accomplished with an entirely new product shows that this expectation has been amply justified. Some of the gears which have been used have been very imperfect, both in matter of material and workmanship, and have been used under extremely trying conditions. That they have not failed has afforded the strongest evidence of the general reliability of the method.

Character of Construction

The character of construction used in this gearing is shown by one of the drawings, Fig. 1. The gear is built up of a number of plates machined to a form which gives them the desired degree of lateral flexibility. These plates are put together, engaging solidly at the hub and also engaging on a narrow edge at the periphery. When so built together they form a solid cylinder which can be spirally cut in the ordinary manner. After cutting, the edge engagements are relieved with a small dividing tool so that each disk operates independently and is free to deflect laterally under the side pressure which results from its diagonal engagement with the pinion. The parts are so proportioned that this lateral deflection can at no time involve fiber strains which could possibly cause destructive fatigue. A very small amount of this lateral deflection is sufficient to afford the desired distribution of load, and this amount can easily be given without approaching dangerous periodic strains.

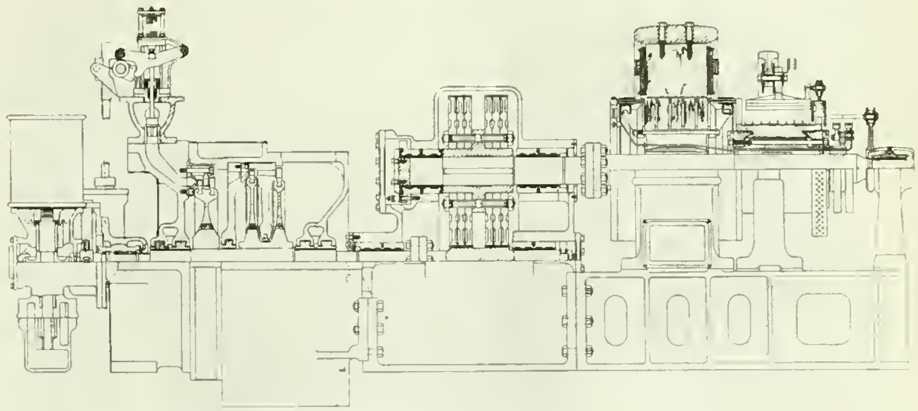

FIG. 5. CURTIS" 300 K.W. TURBINE GEARED TO GENERATOR—5,000 TO 1,000 R.P.M.

Value of Flexibility and Load Distribution

To appreciate the value of this flexibility and load distribution, various peculiarities of solid and spiral gearing must be considered. In the first place, where gears are inflexible, there must always be a tendency to increase strain at the loaded end of the pinion through torsional deflection of the pinion. There is also a tendency to inequality of strain on different parts of the surface through the lateral deflection of the pinion under load. These inequalities can be partially compensated by elevating the bearings or evening the pressure on them, but this compensation can only be partial because the correction applies only to the two ends and not to the middle. Furthermore, the momentary and periodic strains on different points of solid spiral gearing may be seriously affected by vibrations of supporting structures, irregularities of machine work or gear cutting, and other causes. If for any reason such conditions cause any tooth or part of a tooth to receive periodically

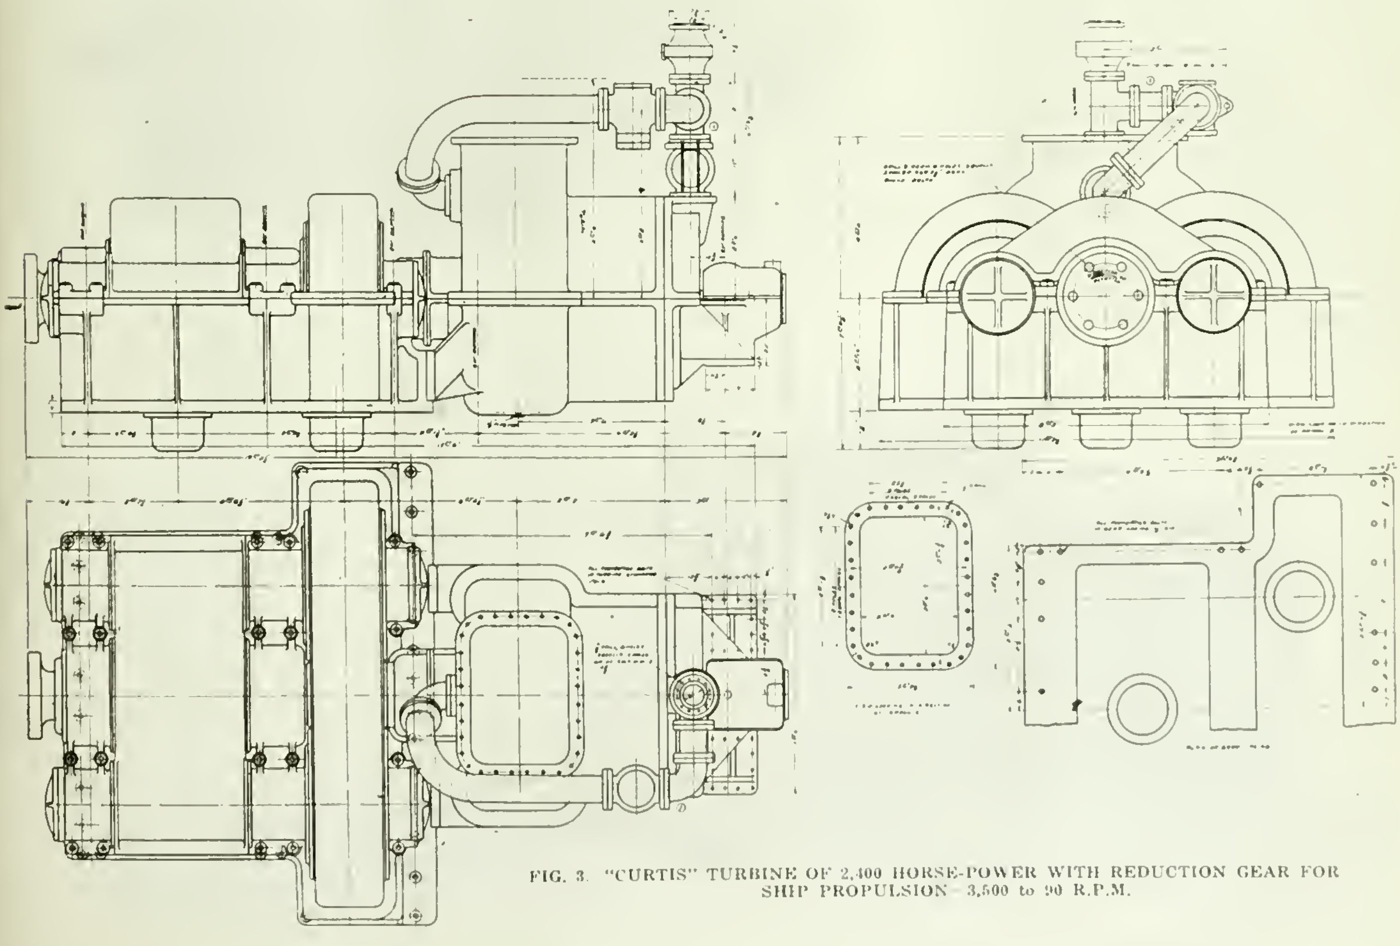

FIG. 3. "CURTIS" TURBINE OF 2,400 HORSE-POWER WITH REDUCTION GEAR FOR SHIP PROPULSION—3,500 to 90 R.P.M.

excessive strains, fatigue may result and a broken tooth may destroy the whole gear.

To obviate the possibility of breakage under such conditions, it is often desirable in solid gearing to use relatively large teeth in order that these possible irregular strains on teeth or parts of teeth will not involve danger of breakage. For other reasons, however, the use of large teeth is distinctly undesirable in spiral gearing. Spiral gears tend to engage by point contacts at or near the pitch line, and the ability of these point contacts to bear pressure without fatigue of the surface metal is governed largely by flatness of the surfaces engaging rather than by the size of the teeth carrying these surfaces. The flatness of the surface is a function of the pinion diameter and not of the pitch. If we double the number of teeth in a spiral gear we have twice the number of driving points in action, and the flatness of all of these points is the same in both cases if the pitch diameters are the same. These matters are illustrated in the sketches in Fig. 1.

With gearing of the Alquist type we can use very small teeth without any danger of incurring excessive strains on individual teeth, which might involve risk of the development of fatigue cracks. In this connection it should be borne in mind that experiments have shown that the strongest steel, if subjected to periodic deflections, will break after a fibre strain of 20,000 pounds per square inch has been applied a million or more times.

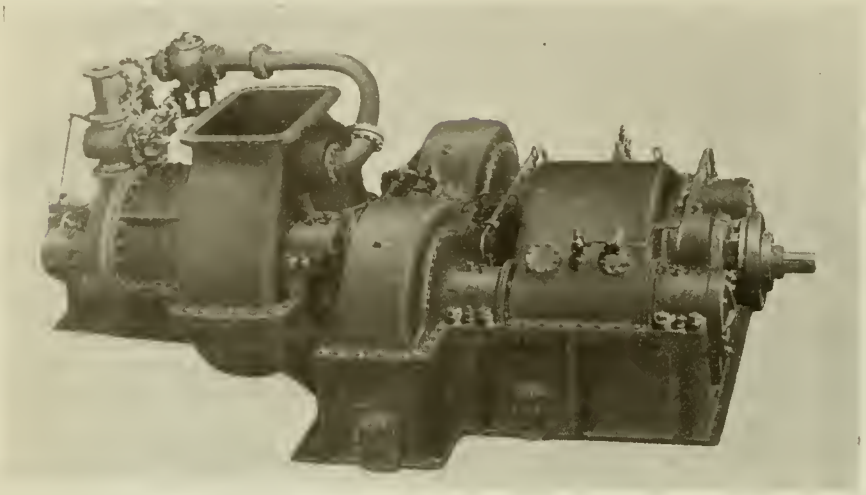

FIG. 6. "CURTIS" TURBINE AND ONE PLANE FLEXIBLE TYPE SPEED REDUCTION GEAR FOR SHIP PROPULSION.

Gear Applications

In the work which is now being done by the General Electric Co. gears of the type described are applied in three ways. First, a single reduction has been accomplished by engaging one solid pinion with a flexible gear of this type; second, by engaging a solid pinion with two flexible idlers, which idlers in turn engage with a solid large gear; and third, in a double reduction where a solid, high-speed pinion engages flexible gears on two countershafts, these countershafts carrying solid pinions, both of which engage a flexible gear on the same low-speed shaft. In these two latter applications the flexibility of the gears serves to equalize the loads between all of the driving points, and the use of a plurality of driving points on the large gear reduces the length of face necessary on that gear. These different methods of application are illustrated by diagrams in Fig. 2, and are also shown by the photographs and drawings of actual machines which are attached to this paper.

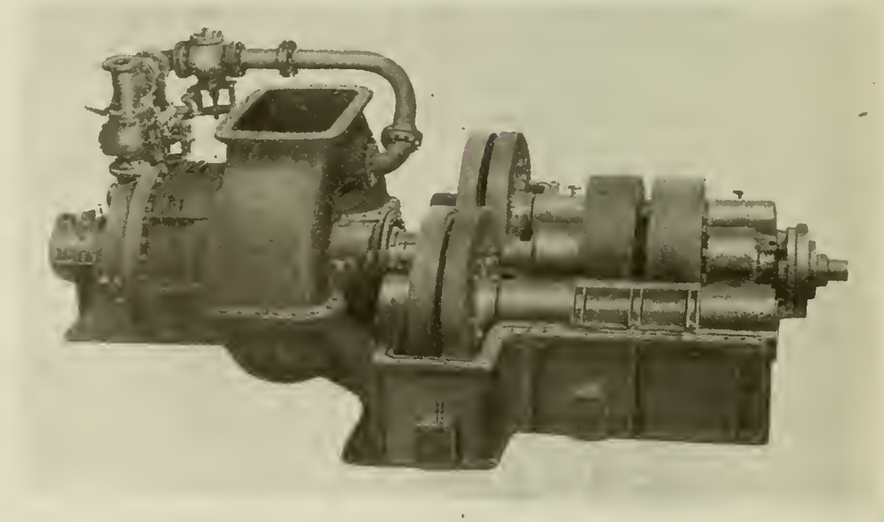

FIG. 7. "CURTIS" TURBINE AND ONE PLANE FLEXIBLE TYPE SPEED REDUCTION GEAR FOR SHIP PROPULSION, SHOWING CONTROL.

In both of these cases where a single high-speed pinion drives two flexible gears, other very positive advantages are accomplished. The pinion is relieved of bending strains, and pressure on the high-speed bearings is avoided.

Experiments have been made in Schenectady which carefully analyze the losses of high-speed gears under various conditions of load and pressure, and these experiments have indicated that low peripheral speeds are more efficient than high speeds. With solid gears, low speeds involve difficulties because they diminish pinion diameters and increase pinion lengths, thus complicating the troubles which may arise through deflection and torsion of pinions and pres-

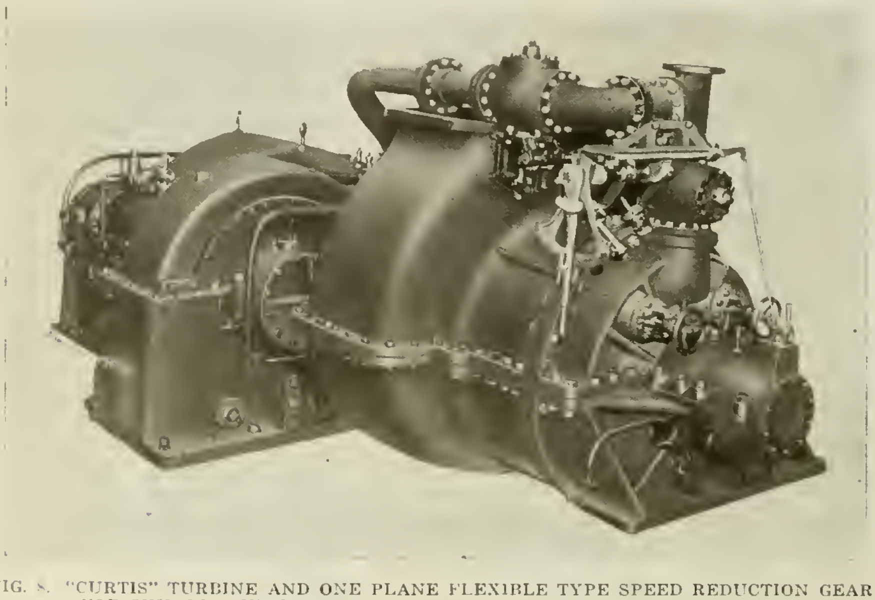

FIG. 8. "CURTIS" TURBINE AND ONE PLANE FLEXIBLE TYPE SPEED REDUCTION GEAR FOR SHIP PROPULSION. TOP HALF OF GEAR HOUSING REMOVED.

sure upon pinion bearings. Since the flexibility of Alquist gears enables us to compensate easily for all possible degrees of torsional yield in the pinion, we can with such gears safely reduce peripjheral speeds by making the gears longer and of smaller diameter. Such reductions of diameter diminish weight and improve efficiency, and the fact that the Alquist method makes such reductions possible constitutes one of its important advantages.

Ship Performance Comparison

The table shows a comparison of performances for two sister ships, the "La Brea" and the "Los Angeles," operated by the Union Oil Company of Los Angeles. Both of these ships are new, carry similar cargoes, and burn the same fuel oil in the same boilers under similar conditions. The "La Brea" is fitted with geared turbine equipment, and the "Los Angeles" is fitted with triple expansion engines of the best type. The "Los Angeles" is equipped with steam-driven oil-handling pumps of the ordinary type, and the "La Brea" is fitted with a new arrangement of pumps driven from the upper deck by General Electric motors. The table illustrates the superiority of the oil-handling machinery as well as that which propels the ships. The horsepower hours given in this table are calculated from the propeller and hull data given by the naval architect of the Union Iron Works who built the ships, and based upon model tank experiments which were made in Washington. The models of the ships are identical, the "La Brea" propeller operating at 90 revolutions per minute and that of the "Los Angeles" at 65 revolutions per minute.

The seventeenth voyage of the "La Brea" and the sixth voyage of the "Los Angeles" were made over the same cource and at nearly the same time. The relation of fuel economy of these two voyages almost exactly corresponds to that shown by the average of all the voyages and tends to verify the accuracy of the whole comparison.

Cuts and data, courtesy of the General Electric Co., Schenectady, N.Y.

THE oldest writing material appears to have been composed of very finely divided carbon in a solution of an adhesive substance, which held the carbon in suspension and fixed it to the papyrus. Ink of this sort has been found on ancient Egyptian papyri, and was no doubt also in use in China at least as early.

AT one time the graphite used for making pencils was obtained almost exclusively from the Borrowdale mines in Cumberland, being mined in compact grey-black masses, cut into thin plates, then into rectangular sticks and cased in wood. The mine was guarded by an armed force, and, to maintain the monopoly, an Act was passed restricting the working to only six weeks in the year; for the remainder it was flooded to prevent theft.

If care be not exercised when sharpening lathe or planer tools on a wet grinding wheel, it is a very easy matter to destroy the cutting qualities of the tools, and this is often done without the knowledge of the operator until the tool is again used upon the work. Excessive pressure should not be used when forcing the tool against the wheel, as the heat generated below the cooling fluid raises the thin edge to a high temperature, and the action of the water causes sudden cooling, often creating minute cracks which result in the failure of the cutting edge when the same is brought in contact with the work. Proper attention should be given to keeping the wheel free from dirt so that it will cut freely without undue pressure in removing metal.

CONTEMPORARY WAR ARTICLES

Embracing Information and Data Drawn from a Variety of Sources Relative to and Arising from the Prosecution of this Many-Sided European War

BRITISH MACHINE GUN FACTORY

THE recent slowing down of certain classes of shell production in Canada is said to be, to some extent, due to the enormous capacity of Britain's home plants which are understood to have proached well on to their maximum production. As is well known, shells have occupied nearly all of our productive efforts in the munition line and admiration for unrestrained and successful efforts by manufacturing concerns have been limited to this work. In Britain, on the other hand, munitions and equipment of all types had to be produced in feverish haste, and after the situation was recognized and the flow of invasion stemmed, organized efforts were put forth on a scale, accomplished with a rapidity. and crowned with a success of which little has become known. It is with considerable pleasure, therefore, that we are able to submit some interesting facts and data regarding one of the new Vickers machine gun shops which has recently been the subject of an article in Engineering, to whom we are indebted for the accompanying illustrations.

As mentioned by our contemporary, the object of publishing the matter is to demonstrate the ready response of manufacturers to meet capital commitments, the energy displayed by all concerned to ensure rapidity of construction and subsequent supply of munitions, and the skill and resource to attain not only the fullest output from a given floor area, but the highest efficiency measured from the standpoint of man-power available.

Extent of Space

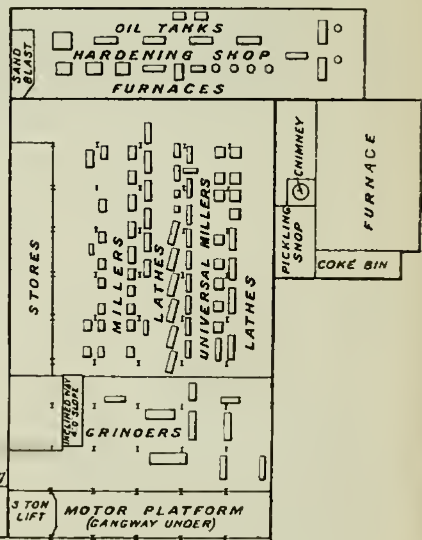
The floor area of the building which contains the plant, is nearly 2½ acres, and accommodates more than 1,000 machines of specialized type, driven by electric power transmitted through the medium of 6,000 ft. of line shafting and 40,000 ft. of machine belting. In spite of the immensity of the undertaking, manufacturing work was commenced within three months of the day when possession was taken of the ground—then a potato field,— while two months more saw the entire establishment in complete working order and a steady supply of machine guns being despatched to the front. Satisfaction of an equally keen type is derived from the fact that all of the machine work in the making of these machine guns—one of the most intricate units of mechanical production—is carried out by women workers.

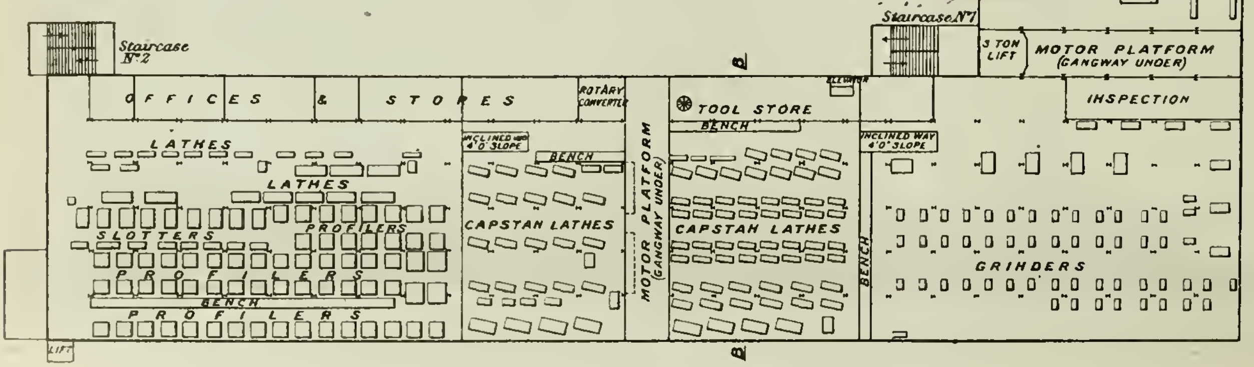
The rapidity with which this thoroughly substantial building was built is due in part to the suitability of the design, and in part to the organizing ability displayed by the various contractors' staffs, while an important factor was the cooperation of the Ministry of Munitions. The design was prepared by the Vickers staff with due regard to facilities for the securing of material. Only in small details was it found necessary to modify the original design.

VIEW IN TOOL ROOM TEN WEEKS AFTER PLACING CONTRACT FOR ERECTION.

Main Building

The main section of the building as shown in plan view has a length of 337 ft. 6 in., with a total width of 75 ft., the spacing of the supporting columns for the upper floors dividing this into 6 bays of 12 ft. 6 in. The outside walls are of brick, with large windows having steel sash. Before the building had been advanced to any extent, it was decided to construct an annex, making the building L-shaped, as shown. The annex has a





LAYOUT OF MAIN FLOOR SHOWING MACHINE GROUPING.

length of 125 feet, and a width of 75 ft.

The ground built on had a natural slope, and in order to avoid the delay and expense of excavation and leveling, the floor level was divided into three sections, with a drop of 4 ft. between each. The floor levels are connected by ramps or sloping alleyways 5 ft. 6 in. wide with a slope of 1 in 5.

LATER VIEW IN TOOL ROOM WITH MACHINES FULLY INSTALLED.

The entire framework of the building is of structural steel, the type of construction being illustrated by the cross-sectional drawing of the building. In all, 266 built-up columns were necessary. The floors were of 3 in. timbering nailed to 10 x 4 in. timbers supported by 18 x 7 in. rolled steel joists, which extend across the building. Brackets and fastenings for countershaft beams, motor platforms, and shafting hangers were incorporated in the column design and fabricated with them at the structural yards. The roof covering is of inch boarding nailed to wooden purlins and covered with fibro-cement slates. Continuous glazing is introduced on the north side of the three bays of the roof, while swinging ventilators are fitted also.

Rapid Construction

In less than eight weeks from the date of signing the contract, the whole of the steel work for the main building amounting to 1,320 tons, was delivered and erected, while less than ten weeks saw the first machine tool under power. The tool room, as a department was actually running within three months from the start of operations. Some idea of the extent of the operations carried out in a little more than three months is given by the fact that the building involved the rolling of $6\frac{1}{4}$ miles of one section of channel steel. There are 248 side windows and 1,350 ft. run of roof windows, the number of panes of glass being 9,500, covering an area of three-quarters of an acre.

In the equipment of the shops with machine tools, etc., equally expeditious work was achieved. The compact arrangement of tools, benches, offices, stores, etc., is shown in the plan view, which is also typical of the arrangement in the two upper floors. Fifty feet of the annex is at the same level as the portion of the main building to which it connects, the remainder of the annex being 4 ft. lower and connected with sloping runway as described.

Department Layout

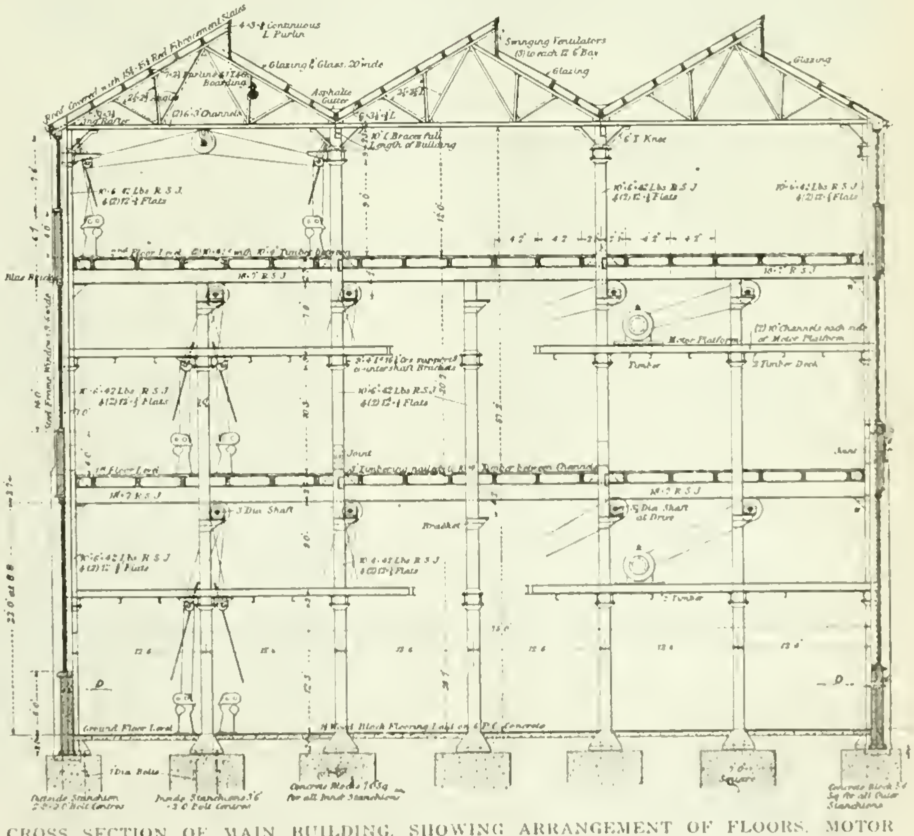
The higher level of the main building and of the annex is used as a grinding shop, where vertical, cylindrical, and surface grinders are installed. The remainder of the annex is given up to millers and lathes for small tool work, while at the extreme end is built a hardening shop with furnaces and oil tanks. The middle portion of the main building is entirely a turret lathe shop, and the third portion is a mechanics' section except for the profiling work. In this latter section lathes and slotting machines are installed along with profiling machines.

On the first floor, about half the area is taken up with a large horizontal milling section, the machines being grouped in types—one block of 120 automatic millers being illustrated. The vertical milling department and the drilling department are also on this floor, which includes further a number of machines for broaching, spline milling, etc.

The top floor is a mechanics' section, half of the space being used for final assembling and the other half as tool room. The top floor of the annex is divided into a number of areas for accommodating finished parts, an inspection department, sand blasting, browning, etc. The two lower floors of the annex are used for the manufacture of small tools, and part of the top floor for the small tools store.

Driving System

The factory is entirely electrically driven, the system being that of using an overhead central platform for taking the motors, which was introduced some ten year ago by this section of the Vickers factories. In this instance the system has been pushed a step further: high-tension current is brought into the building at 3,000 volts from the company's power station on the river bank, which is some distance away, and converted by means of Vickers rotary converters, which are placed at one end of the platform on the ground floor, into 210-volt



CROSS SECTION OF MAIN BUILDING, SHOWING ARRANGEMENT OF FLOORS, MOTOR DRIVES AND SHAFTING DISPOSITION.

direct-current. The controlling switchboard is placed on the motor platform of the ground floor, and direct-current conductors are led direct from the switchboard to the motors on the platform, thus reducing the direct-current wiring to a minimum. This system has the advantage of having the whole of the motors driving the line shafting centralized and under easy observation of the attendant. The electric motors are by the Electric and Ordnance Accessories Company — a subsidiary company of Vickers, Limited —and are placed on each side of the motor platforms; they drive by belts and pulleys, as indicated on the cross-section direct to the line shafting.

BLOCK OF 120 AUTOMATIC MILLING MACHINES.

The line shafting runs in "Cooper" roller bearings supported on brackets riveted to the main columns of the building. Countershaft girders are arranged midway between the machine drive and the main shaft, and the countershafts are supported by special brackets secured to the countershaft girders by hook bolts. All the fittings in connection with rigging up the countershafts are standardized, and any countershaft with the hangers supplied by the machine tool makers can be fitted up without the millwright having to drill a single hole.

The machine tools are of the lighter, accurate variety, and nearly every well-known machine tool maker, producing the type of machinery required, of England and America, is represented, careful consideration having been given to get machines best adapted to the work. In laying out the shop, however, the greatest number of machines of one type have been purchased in order to reduce spare parts.

The building is heated throughout by unit steam heaters with electrically driven fans. The top of each unit is connected by means of ducts with the outside atmosphere, so that the shop floor can be flooded with cool air in summer, or by circulating warm air in winter.

Starting Operations

Equally interesting was the provision made for getting the shop under way as soon as the tools could be installed. This required great foresight, because female labor was to be used to the maximum extent. As a consequence considerable modification in the designs of jigs and fixings had to be made, with the object of simplifying the machining operations. Again, as it was impossible to obtain tool designers and tool makers, a number of the better educated apprentices at the works were drafted on to the re-designing of the methods of manufacture. A section of the old machine gun department was therefore allocated to the manufacture of the jigs and fixings thus designed for the new shop where female labor was to be employed. Where possible, the assistance of tool-making firms was also obtained in order to duplicate gauges and receivers to meet the additional inspection requirements for the testing of interchangeability of the gun component parts. Thus, as soon as part of the building was roofed in the top floor was taken possession of in order to instal the suitable machinery available for use exclusively on tool-making.

To begin with it was decided to concentrate machine work in the new shop on the controlling details of the gun; leaving the other details to be provided by the old shops, while at the same time work was continued to complete the whole range of tools, jigs, gauges, receivers, etc. As the new building developed the manufacture of the remaining units of the gun was added to the original machine operations in the new shop the whole of the machining in this new factory being carried out by women labor. This arrangement achieved a regular growing output without overlap and a minimum expenditure on gauges, receivers, and tools, and conduced also to specializing in the output of certain details in each department, with a consequent rapid production and economy in machine setting.

It is not permissible to indicate the volume of output, but from the foregoing it will be accepted that this new factory —one of many which have been erected since the beginning of the war — once more establishes the enterprise, energy and resource of British engineering. The building is a thoroughly substantial one, and will stand long after the war is over. The machine tools within it are of highly specialized design to undertake specific operations with the exercise of the least measure of intelligence on the part of the operator. There is ensured economy in man-power, extreme accuracy—to one-thousandth part of an inch—and absolute interchangeability. Whether, when the war is over, these tools can be utilized with the same degree of efficiency for peace productions remains to be seen; but it would be a striking reversal of the policy which has enabled such highly efficient factories to be equipped for war work, if, in peace time, the same machine tools, if used for unsuitable work, failed because unsuited in design to achieve corresponding efficiency. However suitable a building, the machine tools used in future for engineering productions must, in practically all cases, be of highly specialized design. This result must be attained even at the cost of discarding otherwise suitable appliances. There can be labor substitution, but not indiscriminate utilization of any type of machine tool for special machining operations.

RECOVERY OF A WRECKED SUBMARINE

THE recovery of a wrecked enemy submarine by the Italian Government in the Adriatic, and its successful repair and entry into the service of the Italian navy, has been accompanied by the publication of much interesting information concerning the doings of the craft, its origin and subsequent journey overland, etc., all of which facts in the light of past events, are conclusive proof, if any were required, of treacherous conduct on the part of Germany toward Italy when their relations were still nominally on a friendly basis. The captured log book gives full particulars of her ill-fated career and other documents establish the fact that she was a unit of the German navy, manned by a purely German crew, and was engaged in active hostilities against Italy many months before that country declared war on Germany.

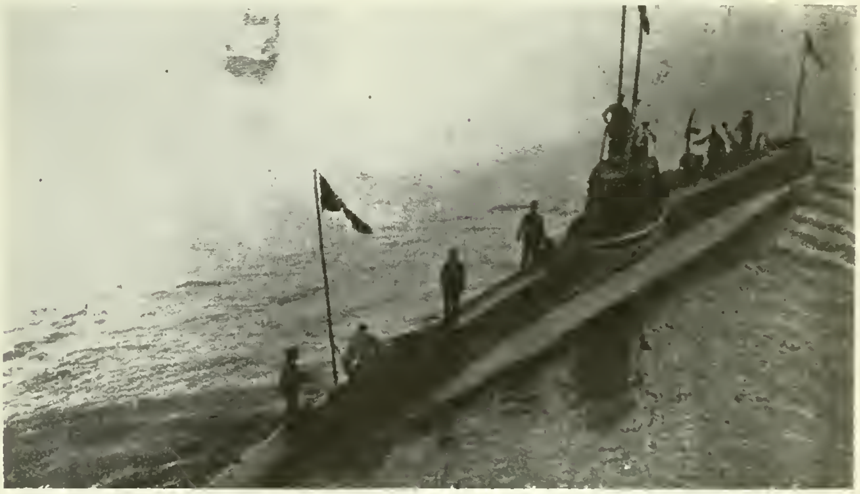
The UC-12 was a small submarine specially designed for laying mines. Her surface displacement is 190 tons, and when submerged is 210 tons. The approximate length is 110 ft., with a maximum diameter of 10 feet. A four-cylinder Diesel engine of 90 horse-power was installed, giving a surface speed of six knots, and a submerged speed of four knots. Six wells in the fore part of the vessel enabled twelve mines to be carried, these being released by a control in the conning tower.

The following report of the activity of

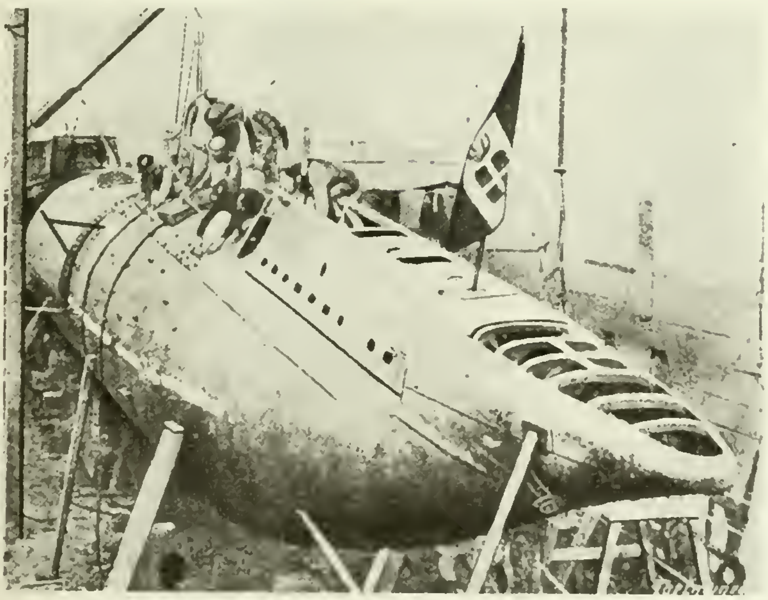
SHOWING EFFECT OF EXPLOSION ON MIDSHIPS SECTION OF HULL.

the UC-12 while in enemy hands has been published by *The Engineer*, the successful conclusion of salvage operations by the Italian authorities being noted with pleasure.

The UC-12, according to her log-book, was one of the first two mine-laying submarines which Germany placed at the disposal of Austria-Hungary for the war against Italy. She was built at the Weser yard, Bremen, all her internal fittings being stamped with the name of Siemens-Schuckert. The launch took place at the beginning of May, 1915, and a few days later the boat proceeded through the Kaiser Wilhelm Canal to Kiel, where she arrived on the 17th, and at once embarked a cargo of mines. A month later, i.e., after Italy's declaration of war on Austria, she was dismantled, divided into four sections, and placed on a train, arriving at Pola on June 24, with her crew and commander. Here she was reassembled in four days, and again took to the water, intact as at first, and, as the Italian Government observes, "German in everything, from the imprint 'Kaiserliche Marine' on every chart to the German Imperial crown ornamenting the table service, and from the cap ribbons of the crew with the three letters B. A. K.—Bekleidungs- Abteilung, Kiel—to the numerous Iron Crosses found in her interior." On July 25 and August 15, she visited the neighborhood of an Italian naval base, and there laid two barriers of mines. In the following December she was at Cattaro, taking on board a cargo of rifles and ammunition, destined for the rebellious Arabs in Lybia. These were duly landed at Baria, near Sollum, on the coast of Cyrenaica, after which she returned to the Adriatic.



THE UC-12 AFLOAT AND IN SERVICE OF THE ITALIAN NAVY.



RECONSTRUCTED HULL APPROACHING COMPLETION IN DRYDOCK.

At the period when there was an abnormal amount of traffic between the two shores of the Adriatic in connection with the transport of the Serbian army, its impedimenta and prisoners — an enterprise which, by the way, was carried out without the loss of a single ship—the UC-12 was cruising off Durazzo, and distributing mines liberally in the roadstead. None of these, however, claimed a victim. After this vain attempt she paid another visit to Cattaro, and then lurked about for three days at the entrance to the Italian base where she had first put in an appearance. Here, it seems, she fouled one of her own mines or blundered into those which had been laid for the defence of the port. At all events, a dull explosion was heard, followed by an immense column of water, and the patrol vessels at once arrived to investigate the phenomenon. Divers who were sent down came upon the wreck of the submarine at a depth of nearly 100 feet. The explosion had blown her practically in two. The extremities were not much injured, but amidships the havoc was very great, as will be seen by the illustration herewith. The bodies of fourteen of the crew were found. Fragments of uniforms were discovered, together with badges, cap ribbons, and other articles, which left no doubt as to the identity of the boat and her crew. A machine gun was also recovered practically intact. The cap ribbons bore such devices as "S.M.S. Vulkan," "S.M.S. Streited," "S.M. Unterseeboot VI.," "2 Minen-Abteilung," etc.

At first sight the wreckage seemed too complete to admit of salvage, but a closer survey convinced the Italian naval engineers that the reconstruction of the boat would offer no insuperable difficulties. The wreck was accordingly raised, in itself a task of no mean order, considering the great depth of the water, and placed on a slip for repair. The mid-ship section, which had caught the full force of the explosion, had to be entirely rebuilt, while at the bow and stern new plates were fitted, the hydroplanes and rudders replaced and the shafting repaired. It is to be presumed that the original propelling machinery was hopelessly damaged, but on this point there is no definite information. Throughout the work special cars seems to have been taken to preserve the characteristic features of the design. What remained of the coming tower was skilfully repaired, and such fittings as were still serviceable were restored. The task was finally completed, and it will be readily conceded that the result, as depicted in our engraving, reflects great credit on all concerned in the work. The UC-12 is now serving as a unit of the Italian navy, thought doubtless under a new name and one less suggestive of her Teutonic origin. It is interesting to note that, according to an official Rome communique of Jan. 13, another enemy submarine, the U-12, was sunk, and has since been salved and placed in commission. This appears to be one of the large German-built ocean-going submarines of 1,000 tons displacement, which had been ordered by the Austrian Government in 1912, and were due to be delivered in 1915. So far as the smaller UC-12 is concerned, the Italian naval authorities are to be congratulated on the highly successful completion of a piece of salvage and repair work which obviously called for no ordinary degree of patience and technical skill.

ORIGIN OF TONNAGE MEASUREMENT SYSTEMS

THE present system of tonnage measurement, known as the Moorsom system, became law in 1854, and, though subse quently amend din detail, remains to this day the basis for the computation of tonnage in all the principal nations of the world.

According to Sir George Holmes, who is quoted by *Syren and Shipping* in the matter, an Act was passed in 1694 for measuring the tonnage of English merchant ships which contained the following rule:

$$\text{Tonnage} = \frac{L \times B \times D}{94}$$

When L = length of keel (so much as she treads on the ground).

B=breadth amidships from plank to plank, in board.

D=depth of hold, as before.

This formula was supposed to give the deadweight carrying capacity of the vessel. The product $L \times B \times D$ expressed, of course, the parallelopipedon of which the sides were the length of keel, the breadth in-board from plank to plank, and the depth of hold, and the divisor 94 meant that every 94 cub. ft. of this parallelopipedon was to be reckoned as one ton. As the true internal volume of the vessel would not exceed six-tenths of that of the parallelopipedon, it is evident that about $(94 \times 6) \div 10 = 56.4$ cub. ft. was reckoned as a ton, and this figure approximated fairly to the value in the time of Henry V. An Injurious Act. The Act of 1694 was repeated two years later, and in 1720 anothe was passed which substituted the half-breadth for the depth of hold. Probably no Act has ever done more injury to naval architecture than the tonnage law of 1720. The half-breadth no doubht represented at the time very approximately the depth of hold; but the law offered a direct inducement to shipbuilders to augment the carrying power of their vessels, without altering the legal tonnage, by the simple expedient of increasing the depth while making no corresponding increase in the breadth, and thus a class of short, narrow, deep and utterly unseaworthy vessels came in existence.

The celebrated Tonnage Act of 1773, which remained in legal force for 62 years, and was still in use in the Royal Navy till as lately as 1872, perpetuated, Sir George goes on to say, the same error. The tonnage, as measured under this Act, was called "Builders' Old Measuhement Tonnage." The length for tonnage was measuhed along the rabbet of the keel, from the back of the sternpost to a perpendicular dropped from the fore part of the main stern under the bowsprit. From the length thus obtained, a deduction equal to three-fifths of the breath (measured as explained farther on) was allowed, and the difference was called the length for tonnage. If the vessel were afloat at the time of measurement, instead of taking the length along the keel, the length of waterline, or of deck was ascertained, and an allowance made by way of reduction of 3 in. for every foot of draught. This allowance was to compensate for the rake of the sternpost, and was independent of the deduction of three-fifths of the breath.

The breadth was measured outside the planking at the widest part of the ship, but the thickness of any doubling strakes was not included. Half of this breadth was taken instead of the depth. Subject to these allowances and differences in the mode of measurement the B.O.M. tonnage law was identical with that of 1720, the devisor 94 having still been used.

Later Development

Between 1836 and 1854, what is known as the "New Measurement" system was in force. The object of it was to obtain a more accurate computation of the cubic contents of those parts of a vessel available for stowage, underneath the permanent decks. The depth was restored as an element in the calculation, but the various lengths, depths and beams were to be measured at *a very few fixed positions*, and this peculiarity of the Act offered owners many opportunities of evading the intention of the law. It is said that in some cases ships built under this Act had a volume of about one-sixth greater than their nominal capacity. The factor of division was 92.4 instead of 94, and in the case of steamships the volume of the space between the engine-room bulkheads was allowed as a deduction from the gross tonnage. The general effect of the Act was to do away with the premium which previous legislation had offered to the building of short, narrow, deep ships; but on account of the many opportunities which it offered for evasion, it was eventually superseded by the Moorsom system of measurement.

CANADA'S TRADE STATISTICS

THE total trade of Canada for the four months of the year, leaving aside the gold figures and exports of foreign produce, was 683 millions, against 499 millions in the corresponding period of 1916, and only 276 millions in the corresponding period of 1915, increases of approximately 40 per cent. and 155 per cent. respectively. But of the gain of 184 millions, as compared with 1916, 115 millions fell under the head of imports, against a 69-million gain in exports.

"National revenues naturally continue buoyant under the large expansion in imports, customs collections in April, for instance, being \$13,875,485, against \$9,797,365 in April, 1916," says the *Journal of Commerce*, Montreal, "but our interest obligations have increased with heavy outlays for war expenditure, and the main dependence for keeping the position steady, while the inflow of new capital for development is checked, rests in establishing and holding a favorable trade balance—in selling abroad a good deal more than we buy."

BRUSH-HOLDERS FOR SLIP RINGS

BRUSH-HOLDERS for metal graphite brushes take forms both foreign and akin to direct-current holders. With these holders the brushes require the usual multiplicity of expensive shunts, the necessity for which, with a proper holder, is at least debatable. Inasmuch as slip ring brushes may be placed indiscriminately around the rings, there is no occasion for maintaining a fixed brush relation to the rings. The ideal holder, therefore, may be in the development of the swivel type, in which the brush may be clamped in the box and the brush itself requires no shunt. The box should, however, be heavily shunted to the holder support in order to protect the swivel from possible arcing due to the current passing through the swivel joints. The brush will require occasional readjusting in the holder due to the wear of the brush reaching, from time to time, the travel limit of swivel. (This limit should not permit the holder to come in contact with the ring). This requirement, however, will not approach the work involved in trimming copper leaf brushes, or in cleaning the accumulated dust from between the brushes and holders, as is necessary with present holders.

At the present time a few slip ring motors are being fitted with a holder of the foregoing type, but the value of its general application has not been fully determined. Present holders are designed to take single brushes, or two brushes side by side, or two brushes in "tandem." The last-named holder is the least desirable for the reason previously stated. However, it has the advantage of economizing the space around the ring and to a degree precluding congestion. Its single objection can he readily overcome by using a partition between the brushes.

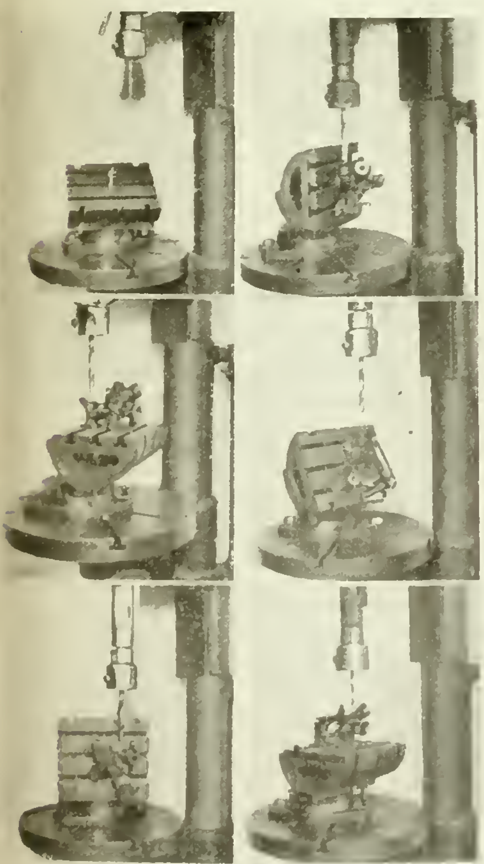
PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

UNIVERSAL ANGLE PLATE

THE efficiency of the modern machine shop is such that the confidence of designers in the ability of most plants to produce work efficiently causes them to frequently arrange parts so that angular connections and surfaces are introduced which formerly would be studiously avoided. Many automobile parts, as well as jigs and fixture construction call for work of this nature and the device illustrated in the accompanying engravings has been developed to meet just such conditions.

The Universal angle plate consists of a semi-cylindrical casting provided with tee slots on its flat side which is the work surface. The cylindrical surface fits accurately into an angle bracket, being tongued and grooved and locked in position by two tee slots as shown. The angle bracket is arranged to swivel on a base plate which in turn is bolted to the machine table. By this arrangement work secured in position may be revolved through 360 deg. horizontally

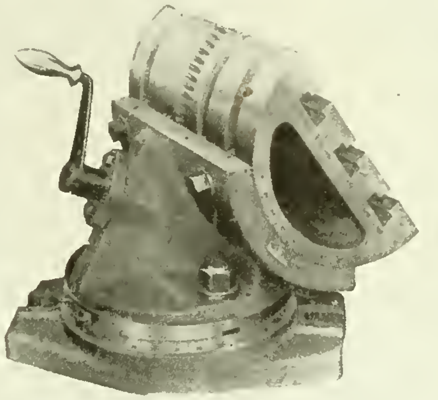


APPLICATION OF UNIVERSAL ANGLE PLATE TO DRILL PRESS WORK

be quickly adjusted to any angle without disturbing work bolted to it, the surface of the work table intersecting the horizontal axis of its rotation.

and 90 deg. vertically. The plate can

Accurate graduations with Vernier attachment permit readings to 5 min., and make it suitable for fine work. The device is built by the Boston Scale &



UNIVERSAL ANGLE PLATE WITH WORM ADJUSTING GEAR.

Machine Co., Boston, Mass., in four sizes, from 4 x 6 in. weighing 16 lbs. to 12 x 18 in. weighing 425 lbs. The two largest sizes have worm adjustment as shown in illustration.

HIGH SPEED BALL BEARING SENSITIVE DRILL

A HIGH speed ball bearing drilling machine with spindle speed up to 12,000 rev. per min., is now being manufactured by the De Mooy Machine Co., Cleveland, O. It is built in both bench and floor types, the latter being shown in the accompanying engraving. The high speed obtainable enables twist drills of 3/16 in. dia. and under to be operated under conditions which enable them to cut their way through material instead of being forced, as is frequently the case when run too slowly.

High grade annular ball bearings combined with properly balanced parts reduce vibration to a minimum. The spindle is 7/16 in. dia., and is of high carbon steel, heat treated. It has a spring counterbalance. Three speeds are provided, the belt cone diameters being 3, 4½, and 6 in.

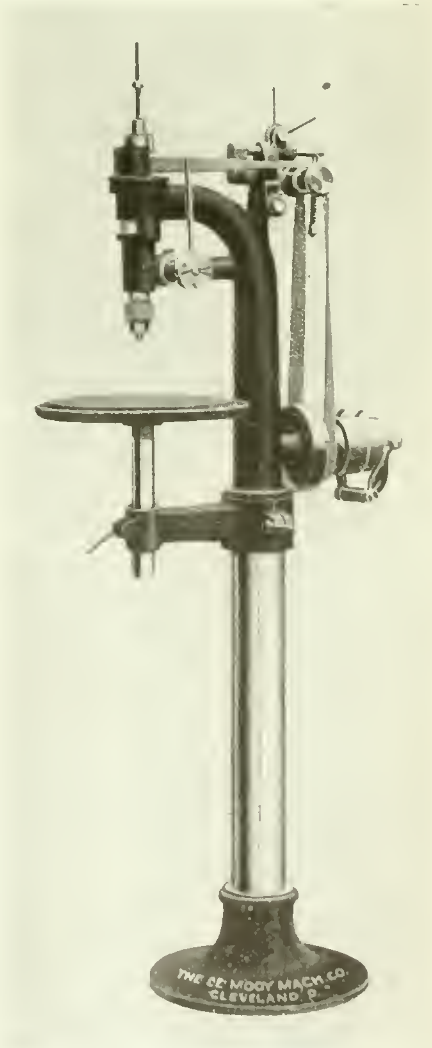
The idler bracket has spring take-up for maintaining constant equal tension in belt, the bracket being controlled by a rack and sector with lever, so that the belt may be instantly slackened to allow of quick speed changes. A flat, endless canvas belt possesses ample flexibility for use at the high speed employed.

A three-jawed, geared-nut chuck of the key type is fitted to spindle. The principal dimensions are: Spindle centre to column, 7½ in.; vertical movement of spindle, 4 in.; ditto, table, 7 in.; ditto, table arm, 25 in.; working surface, table, 12¼ in. dia.; weight, 200 lbs.; height, 65 in.

THREAD MILLING FIXTURE FOR SHELLS

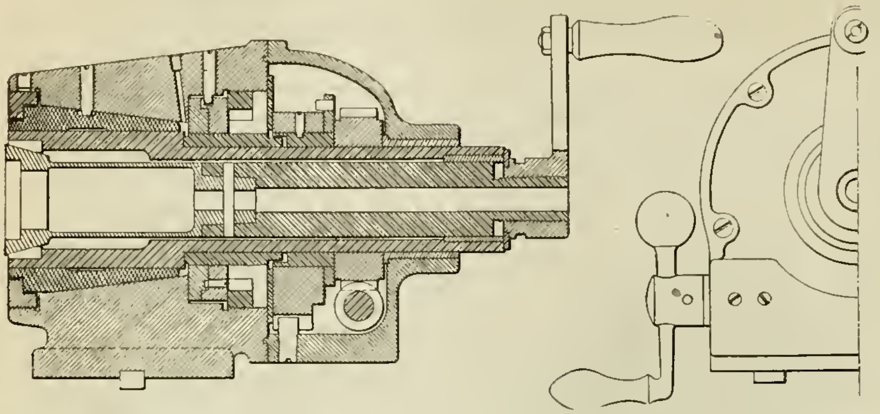
A FIXTURE for producing threads on shrapnel and other shells is being manufactured by the Hall Gas Engine Co., Inc., Bridesburg, Philadelphia. It is designed for attachment to a lathe or milling machine and can be employed for producing either internal or external threads on brass, aluminum, steel or other metals. In addition to being used for munitions work, the fixture is adapted for automobile, firearms, talking machine, and similar plants producing interchangeable parts. Minute accuracy of adjustment for diameter and lead is claimed, as well as elimination of loose joints and provision to insure sufficient lubrication and protection against the entrance of dust.

The fixture is used in connection with a cutter having several parallel rows of teeth so that a single revolution of the work is sufficient to finish the thread.



HIGH-SPEED BALL-BEARING SENSITIVE DRILL.

The work to be threaded is held in a collet at the left of the fixture which is revolved by a sleeve upon which the lead screw is cut. The elimination of loose joints and other sources of inaccuracy is claimed to reduce the error between the lead screw and the nut to less than .0001 in.



WORK TO BE THREADED IS MOUNTED IN COLLET AT LEFT, WHICH IS REVOLVED BY A SLEEVE UPON WHICH THE LEAD SCREW IS CUT.

ELECTRIC GRINDING MOTOR

IN an effort to meet the demand for machines of this type, the U.S. Electrical Mfg. Co., Los Angeles, Cal., has brought out the electric grinding and buffing motor illustrated in the accompanying engraving. While essentially a low priced tool, it possesses pleasing appearance combined with smooth running and silent operation.

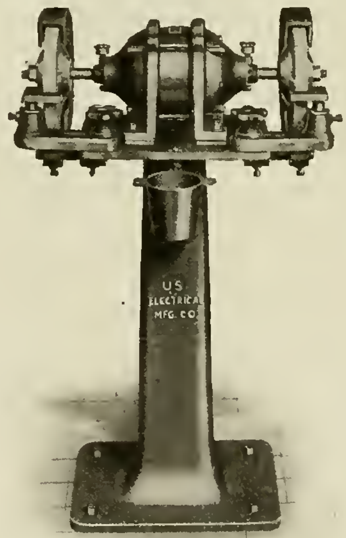
The spindle is carried in ball bearings mounted in special housings with sealing rings that one proof against dirt and grit. The ball bearings are of standard dimensions and easily replaced in the event of wear. The spindle is of heavy one piece construction while the motor as a whole is entirely enclosed. Tool rests, adjustable in any direction, are provided for each wheel; wheel flanges are of ample size and turned all over. Heavy guards are fitted to each wheel and a water pot is supplied which swings under the table out of the way when required.

This tool is furnished either as motor only for bench mounting—motor with pedestal—or motor with pedestal and complete equipment as shown.

Spindle speeds are 1800 and 3,600 rev. per min., and powers are ½ and 1 horse power with 110 and 220 volt single phase current, and ½, 1 and 2 horsepower with 110, 220 and 440 volt, 2 and 3 phase current. Guards take wheels up to 10 in. x 1½ in., length of spindle overall, 25 in., dia. of arbor, at wheels, ¾ in.

BRUSHES FOR SLIP RINGS

THE copper leaf brush for slip rings, which has been in favor since the days of incipient machines, is fast giving way to "block" or "metal graphite" brushes. Generally speaking, metal graphite brushes consist of various mixings of pulverized copper and other metals with graphite, shaped under pressure. When metal graphite brushes were first introduced their carrying capacities were greatly over-estimated. Manufacturers of electrical apparatus dropped into the error of using too few brushes, and in many instances found it necessary to increase the slip ring brush equipment as much as 50 per cent. before satisfactory results could be obtained in the field. At the present time the maximum permissible current is considerably below 150 amperes per square inch, while the safe limit is perhaps under 125 amperes per square inch. This type of brush is also used on direct-current machines of very low voltages. Its metallic characteristics, however, are at times hard on the commutators.



ELECTRIC GRINDING AND BUFFING MOTOR.

As a rule, the more highly graphitized brushes have proven the more satisfactory in that they have a longer life and cut the rings less. It is contended that these brushes are self-lubricating, and to a degree this is true. However, if the rings on which they run are kept free from copper dust, and a slight amount of lubrication (light oil) is judiciously applied, the life of both brushes and rings will in most cases be prolonged. This type of brush is extremely heavy and requires a brushholder of decided stability, with springs capable of pressures as high as five or more pounds per square inch. The actual pressure to be used is determined by the type of ring, speed of ring, and composition of the brush. It is, however, rarely less than three and one-half pounds per square inch, and more frequently five. When brushes of this type are allowed to spark they disintegrate rapidly and the life is greatly shortened.

In case the brush is not sufficiently granular in texture it will "roll up" or "fringe" or form "wire edges" on the sides. Obviously, such brushes are dangerous, for the reason that such edges frequently break away from the brush in full contact length, bridge to, or fall across, rings having different polarities, and flash the machine. To guard against this the brush should be slotted radially with a file, two slots to a side "V" shaped, and about one-eighth of an inch in depth. Under this condition the maximum possible length of thrown-off metal will be something less than one-third of the arc of the brush contact. This is too short to bridge or cause damage. Although a brush may be in every other way satisfactory, if it has this "fringing" characteristic it is not desirable.

Application of Slip Ring Brushes

All types of slip ring brushes should be installed so as to cover the full width of the ring, but never so as to permit the brush to overhang the ring. This is easily accomplished by properly "staggering" the brushes, all slip ring brushholders being designed for this adjustment. Metal graphite or "block" brushes are generally installed radially, and with either one or two brushes in each holder. When two brushes occupy the same holder they should be placed side by side —not in "tandem." If in "tandem," the leading brush is packed against the leading face of the holder by the lagging brush, due to the rotation resultant, and the brushes do not wear uniformly. It may be possible to overcome this by changing the brush angle, or by a change in the resultants of spring pressures. As previously stated, the pressure should be from three to five pounds per square inch.

The conductor was about to give the motorman two bells to go ahead.

"Wait!" shouted an unmistakably feminine voice, "wait till I get my clothes on."

Whereupon seven men rubbered to see a fat woman lift her basket of laundry aboard the car.

* * *

The soldier on the train was dilating on his changed life. "They took me from my home," he said, "and put me in barracks; they took away my clothes and put me in khaki; they took away my name and made me 'No. 575'; they took me to church, where I'd never been before, and they made me listen to a sermon for 40 minutes. Then the parson said, 'No. 575, art thou weary, art thou languid?' and I got seven days C.B. for shouting 'Not a dam bit.'"

MORE PUBLICITY CONCERNING OUR SHIPBUILDING EFFORT

IT is highly significant that little, if any, disposition is being shown by Canada's shipbuilding and shipping executives to take part in the daily press controversy relative to what this Dominion can or should do to help offset the meantime ship shortage emergency. That a full appreciation of all the circumstances is theirs, little doubt may be entertained, therefore, silence on their part seems golden. In the House of Commons, Ottawa, on June 1, the Hon. J. D. Hazen, in his replies to a number of queries concerning shipbuilding within our borders, gave some specific instances of the activity prevailing as regards both wood and steel construction. As was to be expected, however, the information imparted was in no sense satisfying to the exponents of the one-ship-a-day policy so firmly believed in and fondly cherished by the craft nondescripts.

Canada is doing a good deal more in the realms of shipbuilding and marine engineering than the Minister of Marine and Fisheries made public, although doubtless his immediate audience knew that such was the case and were more or less familiar with the complete detail. To continue to withhold information, however, as to the full scope of our shipyard and engine-works activities is, it seems to us, causing unnecessary apprehension on the part of our citizens generally that a capacity output is not being realized, besides tending to reflect on and in turn irritate those charged with the administration of our various plants. The restraint put upon the publication of our munitions activities when first undertaken was of brief duration, yet while the privileges later afforded were wide in scope and might easily have been abused, no awkward situations developed; rather did the publicity feature become of material benefit, stimulating as it did both effort and its result value.

Our ship and engine builders are not only working to the capacity of their plants at the present time, but their showing as regards progress and output is equally satisfactory with that of munitions. The reserve being shown relative to plant establishment or to schemes of enlargement is logical, in view of the fact that in half a decade or even less, following the Peace Declaration, our position will be world competitive in shipbuilding, an eventuality not lightly to be overlooked. Present conditions are entirely abnormal, and to cope with same without consulting the future as some would have us do, is to ensure that much of the capacity for the abnormal would speedily become grass-grown later. We'll never be a shipbuilding nation worth-while, until we can produce the steel in its variety type and form for vessel, engine and boiler construction requirements, which leads us to say that our first duty, because it is our biggest need, is the planning and initiation of enterprise in that direction.

As it is, we are under the necessity of importing practically everything that enters into steel vessel construction, and same is true to about the same extent as regards equipment, propelling and auxiliary machinery. The delays in receipt of material are equally abnormal with the times, nor are such circumstances to be wondered at when account is taken of the fact that the United States, on whom we depend so largely for the requisite supplies has a shipbuilding programme of prodigious dimensions of its own on hand, and may readily lay claim to first call on its steel mills, blast furnaces, forges and coal mines.

With a view to allaying the misgivings and unrest arising from the lack of public knowledge as to what Canadian ship and engine builders are doing to help eliminate the shipping emergency, we suggest that permission be granted them to furnish authoritative data for publication, subject, of course, to somewhat similar and equally reasonable restrictions as have been operative in our munitions industry.

PRESENT INFLUENCES ON MACHINE TOOL ACTIVITY

SHIPBUILDING, no less than shell making, is destined to influence the tool industry of Canada. There is this difference, however. In munitions manufacture the demand for tools was so insistent and imperative that neither designs nor resources were immediately available for the production of other than standard type tools. Months passed before the combined effort and consideration of producers resulted in the flow of those special purpose machines which have changed the whole aspect of quantity machine work.

It is not expecting too much, to hope that a similar development, more rapid and timely, will occur in connection with shipyard and engine shop equipment. Many firms engaging in these lines are untrammeled by tradition or precedent, and, provided that the requisite quality of workmanship be maintained, the freer perspective enjoyed by these concerns, coupled with the example of the munitions industry, should result in innovations of considerable calculable benefit to both machine tool builders and shipbuilders.

The demands of the situation prompt the suggestion that well designed tools of the heavy portable type will prove of considerable value. By moving them around to work in various locations, the necessity for extensive handling plant will to a great extent be avoided, while their adaptability to operations of more diverse character, with greater facility than permanently located tools of stereotyped design should result in their adoption by those plants whose activity in this work is more or less temporary. Several suitable designs have been marketed during recent years, but if history repeats itself, a good deal of development in this direction is due to take place.

The General Market Condition and Tendency

THERE is apparently no limit to prices of pig-iron as all indications point to further advances. A price of $50 for Bessemer iron has been established at Pittsburgh and the market consequently is in an excited condition. Quotations of domestic pig-iron are still temporarily withdrawn, due principally to the unsettled coke situation. Coke is very high in price and supplies are not coming forward from the ovens in sufficient quantities to fill requirements. The outlook as regards coke is not at all favorable, and is causing considerable anxiety. The steel market continues strong with prices very firm. Prices of a number of steel products have recently advanced in the United States, which will doubtless be reflected in Canada shortly. The requirements of steel for war purposes are increasingly heavy and consequently steel for general purposes is becoming more difficult to obtain. The outlook for the private consumer is thus becoming more serious. Coal continues high in price and a serious situation is anticipated unless a determined effort is made to increase the supply. Prices of galvanized sheets have advanced again, but black sheets are unchanged in the meantime. There is a shortage of black sheets, as the American Government is taking over a large percentage of the output of the mills, leaving a comparatively small tonnage available for the private consumers. The non-ferrous metal markets generally are firm, but business is dull. Lead is very strong and higher, due to scarcity of supplies. Antimony is weaker and lower. There is no change in the scrap metal situation this week, although it is likely that prices of cast iron scrap and heavy melting steel will advance on account of the heavy demand. Coppers are inactive and demand light, but lead scrap is firmer. The demand for machine shop supplies continues active at firm prices, with a few advances. A fair demand for machinery for general purpose features the machine tool market.

Montreal, Que., June 11, 1917.—Despite the fact that steel requirements have apparently fallen off owing to the curtailment in the manufacture of the heavier shells, the scarcity of steel is more marked than ever, and the general situation is seriously menaced by the shortage of raw materials. As the demands during the next few months are expected to increase, the outlook for the immediate future is not encouraging, although every possible facility is being adopted to give relief to the situation. The present political situation tends to keep matters in rather an unsettled condition which can only be relieved when the pending developments take tangible form. Both the labor and coal situations possess continued interest because of their vital importance to the steel industry.

Pig Iron

The pig iron market continues to advance, reflecting very emphatically the actual condition of the iron and steel situation. The American market generally has advanced over $2 per ton, with the Pittsburgh quotations figuring in the recent rise; Bessemer has advanced during the week $7 per ton, the current quotation being $53.95 per ton. Basic, at $48.95 per ton, shows an advance of $6 on the week. A similar advance on forge has brought it also to $48.95. Foundry and malleable has been advanced $3, the present price being $48.95. Canadian producers continue practically out of the market prices being withdrawn.

Steel

Another sensational week has passed in all branches of the steel situation and the markets are much stronger. The trend of future conditions is indicated in the transactions of the past week, as the developments in the Pittsburgh district are examples of what may be expected in connection with the steel industry during the coming months. The insistent and ever-increasing demand for steel of all kinds and the evident scarcity of scrap and old metal for remelting, would indicate that the prices of the future may far outrun any that have yet been announced. The situation is fast coming to the point where any but war requirements and those closely associated with its prosecution, will of necessity, require to be indefinitely delayed, owing to high cost of all kinds of materials. The American Government is still working on war plans and the steel and other requirements that will eventually be required, large orders for which are being placed as rapidly as possible. The shipbuilding programme is probably one of the most important and it is estimated that facilities will soon be provided for rolling sufficient steel for the construction of one 3,000-ton steel vessel per day. It is this situation that is making it so difficult, if not altogether impossible, for domestic users to secure steel. The changing conditions in the States is gradually producing a labor shortage that in time may have considerable bearing in manufacturing circles. The Canadian situation in this respect, while not very serious, is, nevertheless, quite acute, but has been somewhat relieved by the decline in the production of heavy shells; some firms, however, that were engaged in this business have continued to utilize much of their old force for the production of steel for other purposes. The lowest price quoted for Bessemer sheet bars is now $100 Pittsburgh, and early advances are not unlikely. The Pittsburgh quotation on iron and steel bars has been advanced $5 per ton, the price quoted being $4.25 per hundred. The present market in blue annealed and black sheets is very firm with a strong undertone tending to higher prices within a few weeks. The Pittsburgh quotation on galvanized sheets has advanced $6 per ton, the current price being approximately 10 cents per pound. The demand for shafting continues to be quite heavy, the discount being closer than the previous week, in some instances being only 5 per cent. off list. Following the constant rise in the cost of raw materials, the quotations on wire products have again been advanced $5 per ton; plain wire is now $3.70, galvanized wire, $4.40, wire nails, $3.75 and galvanized barb wire, $4. Local dealers have not yet revised their prices, but may do so in the very near future. Owing to the shortage of prompt furnace coke and the difficulties contingent to deliveries, the market is very strong with the spot quotation 75c per ton higher than last week; the price now asked being $10.25 per ton. The general situation in this district is practically unchanged and the market is very firm.

Metals

The market has been comparatively quiet during the past week, but prices have been well maintained. The situation is being influenced by pending developments in the States and unsettled conditions will likely prevail until the plans of the government are completed and the requirements definitely announced. Copper is quiet, but the market is strong. Tin is easier abroad but is firm here. Spelter is active for futures but quiet on spot. Lead continues to remain firm with a stronger tone. Antimony is easier on better supply. Aluminum is steady and unchanged.

Copper.—The recent demand for copper has been rather quiet. The trade appears to be awaiting the decision of the American war department regarding future requirements of copper. Sales of second-hand metals for early delivery are the feature of the market, being brought about by prevailing high prices. New York prices are firm at last week's quotations, and dealers here are still quoting those of the previous week, 38½c for lake and electro, and 37½c. for castings.

Tin.—The situation has been featured by a marked decline in the prices quoted for this metal, both on the London and New York markets. The possible cause for this may be accounted for by the possibility that shipping permits from England may be more easily obtained, and the fact that the transportation risk has apparently been decreased. The sharp decline on the London market has also been a factor in the easier tone in New York; the quotation on the latter being now 61c. per lb., a decline on the week of 3c. per lb. Dealers here are quoting 62½c. on a steady market, but the undertone is weaker, especially for large quantities.

Spelter.—A peculiar situation now features the spelter market in the fact that the spot market is easier than for futures, but this condition is becoming less prononunced as the producers take a more optimistic view of the future. Operating conditions, both in the ore fields and at the smelters, are not favorable for any further decline in the price of this metal, and producers are holding out better hopes for the future when the plans of the American government are further developed. New York continues to quote 9⅝c. on a quiet market. Dealers here are quoting 13c. on small quantities, a decline of ½c. per lb.

Lead.—The firmness of the market is well maintained and the scarcity of the supply is one of the main factors for the strong position of this metal. Increased facilities for production in the near future afford some relief to the outlook for this metal, but at present the market is increasing in strength. A further advance has been noted on the New York market, the trust price having advanced one cent and the independents ½c. per lb.; prices quoted being 11 and 12 c. respectively. The market here is also stronger, an advance of ½c., bringing the price up to 14c. per lb.

Antimony.—Less demand and increased supply has developed a weaker market and prices have, therefore, declined. New York is quoting 21c., this being 1½c. lower than a week ago. The local market is easier and prices quoted are one cent lower than last week, the dealers asking 25c. per lb. on small lots.

Machine Tools and Supplies

No feature of special interest has developed to alter the general machine tool situation and the market continues to reflect more normal conditions in every direction. The demand for munitions machinery during the week just passed has shown slight improvement over that of the previous week, but the requirements for this purpose are now largely for those plants that are increasing their present output, or where it has been found necessary to replace old or obsolete tools. Apart from the munitions demand, however, the requirements for general purposes continue to show a marked increase, and in this connection it might be said that the trade generally would probably be considerably greater but for the higher prices that are constantly being asked for all classes of equipment, this being a necessary factor owing to the excessive cost of all raw and semi-finished materials.

Scrap

An evident scarcity has developed in pig iron and steel scrap and the market in these old metals has become stronger with the continued heavy demand. The general tone of the market has an upward tendency as the insistent requirements for steel of every description make it imperative that productive be maintained no matter at what cost. Firmness prevails in the local situation, with steel-making scrap very strong and advancing; No. 1 machine composition has been advanced 1 cent, the present quotation being 22½c. per lb. Steel turnings show a similar advance, the price quoted being 9c. per lb. Machine cast iron and malleable scrap have been advanced 3c. during the week, the current quotations being 25 and 20c. respectively. Heavy lead is one cent stronger at 11½c. per lb. Aluminum on a 3c. rise is quoted at 35c. per lb.

Toronto, Ont., June 12.—That a price of $50 has been paid for Bessemer pig at Pittsburgh is a matter of considerable importance, as it shows distinctly the general trend of prices, not only of pig iron, but also of steel. Less than one year ago the same grade of iron was selling at around $18, so that in a comparatively short time the price has been nearly trebled. In some quarters it is firmly believed that the $75 mark will be reached, which is not at all unlikely in view of prevailing conditions. The cause of the extraordinary high prices of pig iron is due to the law of supply and demand, and not to any artificial boosting.

Steel

Notwithstanding the prevailing high range of steel prices there is no sign that the top has been reached, in fact all indications point to a continuance of the upward movement for an idefinite period. The recent advance in prices of many lines of steel products in the States will doubtless be reflected in the Canadian market shortly. The $50 mark for Bessemer pig iron has been reached at Pittsburgh and created a situation which is bound to affect prices of steel. Higher prices on iron and steel bars and structural shapes are looked for in the near future, while an advance on wrought pipe is likely at no distant date. Pressed steel spikes have advanced and are now quoted at $7 for ¼ in., and 5-16 in., and $6.50

for ⅜ in. and larger. Cut nails are also up, being now quoted at $5.35 per keg base. Plate washers are now net list as against 10 per cent. off formerly. The steel plate situation continues very tight and material is more difficult to obtain than at any time before. Prices are practically nominal as it is almost impossible to quote prices on plates that are accurate, and that correctly represent the market. On nearly every sale of plates that is made, the mill takes into account whether the buyer is a regular customer, what the plates are to be used for, and the deliveries wanted. The present enormous demand is largely for ship construction and the market is practically dominated by the American Government requirements of plates for this purpose.

The shortage of steel is becoming more acute as requirements for war purposes are growing heavier. The high cost of steel and difficulty of obtaining supplies is tending to curtail the demand for ordinary purposes. Private consumers cannot obtain material in sufficient quantities and are thus in many cases severely handicapped in operating their plants. Deliveries are getting more backward all the time and the delays in getting steel, although unavoidable, create a difficult situation for the manufacturing consumer to contend with.

As Government requirements of sheets have monopolized output of the mills in the States, makers are having the greatest difficulty in providing for their ordinary customers. The demand for sheets for Government war requirements is increasing rapidly; in fact, makers are finding it more difficult to provide for tonnages as they come out. Only quite a few mills are in the market, and they are offering only limited tonnages at comparatively high prices for nearby shipment. Prices of black sheets are very firm and may advance any time. Galvanized sheets have again advanced, Premier No. 28 being quoted at $10.70, and 10¾ oz., at $11.50.

Prices of steel products in the United States have again advanced, affecting principally iron and steel bars, skelp, open-hearth sheet bars, and forging billets. The problem at the present time is to apportion the requirements of steel so as to give a fair share and to provide at the same time for the urgent needs of the American Government and the Allies. The rail market is particularly strong. Large orders for rails from Russia, Great Britain and France have recently been placed with U.S. mills. Conditions in the rail branch of the steel industry are such that there must necessarily be a long delay before orders in prospect can be filled. The earliest shipments that can be hoped for will hardly be before the second half of 1918, and the balance will run into 1919. The unfilled tonnage of the U.S. Steel Corporation on May 31 was 11,886,591 tons, being a decrease of 296,492 tons from April.

Pig Iron

The genuine scarcity of pig iron which is generally acknowledged to be serious has brought into the market many buyers who have hesitated. There seems no doubt as to the stability of present prices notwithstanding the high level reached. There is apparently no limit to prices. The long predicted price of $50 for Bessemer iron has been established, this being the current quotation for this grade at Pittsburgh. The steady advance in prices of pig iron is due partly to high cost of fuel and coke and continued shortage of labor, in fact the cost of everything having to do with the production of iron has gone up to extraordinary heights. The principal reason, however, for the high price of iron is the question of supply and demand. More iron is wanted than the furnaces can supply. Local prices are still temporarily withdrawn owing chiefly to the uncertain coke situation. Connellsville coke which was selling a year ago at $2.75 is now firm at $10 ovens. Supplies are also uncertain and causing considerable anxiety to consumers.

Scrap

The market is quiet and prices unchanged on the basis of last week's quotations. Business has been dull during the week. It is possible that prices of heavy melting steel and cast iron scrap may go higher. There is a scarcity of both these materials and in view of the heavy demand it is likely that prices will advance. In the meantime quotations are firm and unchanged.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the Commission headquarters are at Ottawa.

Machine Tools

Nothing of particular importance has developed in the machine tool market. Business is gradually assuming a more normal aspect and the demand for tools for general purposes is the principal feature. Canadian machine tool builders continue to be steadily employed on both domestic and export business, the situation in this respect being satisfactory.

Supplies

Business continues active at firm prices. Cast iron and malleable fittings have advanced. Machinist's and parallel bench vises have been advanced approximately 10 per cent. An advance of 10 per cent. has also been made in brass globe, angle and check vales.

Metals

Although trading in metals has not been particularly heavy during the week the markets generally have been firm and prices well held on the basis of last week's quotations. An exception must be made, however, in regard to antimony, which has declined, while on the other hand lead has advanced. Some uncertainty prevails in the metal market as the American Government requirements have not yet been made known, but it is generally believed that the Government's buying will be heavy, and in anticipation of this the markets are firm and buoyant. Lead is the most interesting of the metals just now owing to its strong position and steady advance in price. Copper continues stationary and the market is quiet, waiting developments. The excitement in the tin market has passed off, but the market is holding steady with buyers holding off also waiting developments. Spelter is quiet and unchanged, as is also aluminum. Higher prices on solders may be looked for if lead continues to advance.

Copper.—Buyers continue to hold off pending the long-expected announcement, which is due shortly, with regard to the requirements of the American Government for copper. In the meantime the market is nominally unchanged. The earlier positions up to August are all sold up by the leading producers and can only be obtained in limited quantities through brokers and dealers. The undertone of the market continues strong. Copper is quoted locally as follows: Lake and electrolytic, 37c, and castings, 36c per lb.

Tin.—The market is steady and prices although unchanged may possibly decline in the near future on account of the easier situation in New York. This is due mainly because demand is light, arrivals have recently been fairly large and shipping permits are likely to be more readily obtainable. Advices from Washington announce that new arrangements are pending between the British and American Governments whereby there would henceforth be a more equitable allotment of tin btween consumers in the United States. The benefit derived from this will be reflected in the Canadian situation. Local quotations are unchanged and nominal at 66c. per pound.

Spelter.—Business is dull but quotations are firm with indications of higher prices. The opinion is held in some quarters that a decline in prices is unlikely under present operating costs and that any improvement in demand would send prices up. Local price 12c. per pound.

Lead.—Continued strength characterizes the lead market and the price has again advanced. The "Trust" has advanced its price to 11c. New York, while "Independents" are quoting 12c. New York. The demand for lead has been very heavy and as the leading producers have offered none for sale for many weeks, consumers had to depend on independent concerns. The market at once began to stiffen and has been growing stronger and higher ever since the withdrawal of the leading producers. Lead has advanced ½c. locally and is now quoted at 14½c. per pound.

Antimony.—The market continues quiet with lack of demand for prompt antimony, although there is a growing demand for future shipments. The local situation is weaker and the price has declined 4c. to 26c. per pound.

Aluminum.—The market is firm in anticipation of heavy demand for war purposes. In the meantime quotations are unchanged at 68c. per pound.

Sydney, N.S., June 9.—The Glace Bay collieries of the Dominion Coal Co. produced in May approximately 328,000 tons, comparing with 353,000 tons in May, 1916. The aggregate production for the first five months of the year shows a decline of 225,000 tons when compared with the corresponding period of last year. Indications are, therefore, that the first half of 1917 will show a reduction in production from 1916 of almost a quarter of a million tons. The rate of decline in the second half of the year will not be so marked, as the monthly tonnages will then compare with a period of 1916 when the decline in outputs had become very pronounced.

A large amount of coal is stored on the ground at Glace Bay, and stocking is still proceeding because of the lack of shipping tonnage to transport the coal to a market. It is an unprecedented circumstance to be stocking coal in June, and, of course, this procedure cannot long continue, as it would be dangerous practice to stock fresh mined coal in the hot weather. The shipping shortage is the result of admiralty requisitioning of the coal-shipping fleet.

The Mines Branch have deputed J. G. S. Hudson, of that Department, to investigate on the ground the questions of coal production and transportation in Nova Scotia. There should be very little difficulty in this investigation, because two factors only are involved, first, a shortage of mine labor, and second, a shortage of transportation facilities both by rail carriage and water freighting. The first condition is not capable of remedy during the continuance of the war. Because of the restriction of enlistments among miners, the decline in outputs has been to an appreciable extent arrested, but no increase in production is possible. The matter of transportation is capable of remedy, if suitable action is taken by the authorities in charge.

The prospects of a coal famine in Canada become daily more evident and inevitable. Conditions among coal consumers and the poor in the large cities of Canada next winter will be such as to justify the most serious apprehension among those who realize what is coming. Coal operators in the United States will not make contracts to-day, and will not in many cases even quote. A large coal dealer in the Maritime Provinces recently sent out in one day thirty-six telegraphic enquiries for coal quotations to operators in the United States. Replies refusing to quote were received from eighteen operators, and the other eighteen did not bother to reply. This is a typical case, and many others could be adduced.

In face of these conditions a coal strike in the Western collieries, and the possibility that Nova Scotian collieries may have to curtail production because of lack of transportation, seem to call for some serious thinking and definite action by whatever powers may be in these chaotic days.

Pittsburgh, Pa., June 9—There is no longer any buying of consequence in steel products for far forward delivery—the only delivery the large steel mills can make, as they are sold up in their various departments for an average of about ten months, some farther than that, some not so far. Evidently buyers do not care to take chances, nor mills make contracts, so far ahead. Prices formerly recognized as the regular market "for delivery at mill convenience" have, therefore, practically disappeared, and such market as exists is made by mills not completely sold up, chiefly the smaller establishments, who can arrange for some deliveries in from three to six months. For such, prices are, in many instances, higher than those of a fortnight ago.

For delivery a few months hence, prices are approximately as follows: Merchants bar, 3.75c. to 4.25c.; structural shapes, 4.25c. to 4.50c.; tank plates, 7c. to 8c.; ship plates, 9c. to 10c. or higher; wire nails, $3.50 to $3.75; hoops, 4.50c. to 5c.; blue annealed and black sheets, 7.50c.; galvanized sheets, 9.50c. to 10c. These prices are generally named only to domestic buyers, there being little disposition to quote on export business. There is ground for suspicion that the market is already lining itself up for a decline in prices as it has already had a decline in activity, though not, in all probability, in less than about five or six months from now.

War Steel

The present outlook is that a larger proportion of the steel output will be marshalled for war purposes than was estimated at the outset, when 20 per cent. was considered altogether an outside estimate, and 10 per cent. was regarded as possibly excessive. In the first place, the view is much more general that the war is likely to last one, two or more years still. In the second place, the amount of steel needed for transportation purposes is very much larger than anyone assumed even a few weeks ago. The information furnished by the British, French and Italian Missions is perhaps responsible for this change in appraisal, while the collapse of the wooden ship program accounts for a large quantity of steel that will be used in building small steel freighters.

For instance, while orders for 500 locomotives and 10,000 cars were arranged recently for Russia, under the auspices of the Advisory Commission of the Council of National Defense, the Commission, working through a car committee of which S. M. Vauclain is chairman, is negotiating with the car builders for a total of no less than 100,000 cars. Where these cars are to go is not stated, but it may well be assumed that they are to go chiefly to Russia and France, with probably a fair proportion to be placed on American roads, which are themselves in need of cars. There is no word of similar negotiations as to locomotives, but that will no doubt come also.

The tonnage of sheets required promises to be large, quite in excess of most recent estimates. It turns out that sheets are a particularly useful form of finished steel for war, as there are sheet requirements for tent pins, tent stoves, camp ranges, ammunition sheds, aeroplane hangars, helmets, mines, net floats, and probably various other things of which we have not yet heard. The Government buys the finished products and the factories involved buy the sheets, exhibiting the necessary documents whereby a concession in price—not stated—is granted, and a committee of sheet manufacturers is to see that the participation of the various mills is in proportion to their capacity.

The scarcity of sheets produced by the filling of these requirements may not be as severe as was expected. Automobile makers foresee a smaller demand for pleasure vehicles and some have already curtailed their specifications to mills. Hudson is going to abandon pleasure cars entirely and will make trucks only.

Pig-Iron and Scrap Famine

By far the most important development in the general iron and steel market is the famine, or prospective famine, in pig iron and scrap. There have been large increases in steel-making capacity, but scarcely any in blast furnace capacity, while on account of deficiency in coke supplies, due to car shortage in the Connellsville region, pig iron production was greatly curtailed in the winter, by close to 10 per cent., and even in the past two months the supply has not been fully adequate, as with more furnaces in blast the output has been somewhat less than in last October and November. Until recently the whole matter of production has been one of steel-making capacity, there being plenty of pig iron for the Bessemer converters and open-hearth furnaces, and plenty of rolling capacity to turn the ingots into finished products. Now the thin neck of the bottle is to be the blast furnaces instead of the steel-making departments, unless all signs fail. The production of steel the remainder of this year will be larger than in the same period last year, but the limit will be determined not by the steel-making capacity, but by the raw materials available.

One More Thing.—Pat and Bridget were being married, and the whole village was astir. Pat was resplendent in a tail coat (borrowed), patent leather boots (too tight for him), a white vest, and a bright green tie; Bridget shone glorious in most of the colors of the rainbow.

The fateful words were spoken, and the happy pair walked down the aisle and out into the street, where a great crowd greeted them with loud cheers.

At last they were safely ensconced in their cab, and Bridget sank back with a sigh of satisfaction.

"Sure, Pathrick," she said sadly, "there's only one thing Oi regret. If we cud have stood on the pavemint and watched ourselves pass, wouldn't it have been hivinly?"

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

ENGINEERING

Princeton, B.C.—The British Columbia Copper Co., will install a power plant and mill shortly.

Toronto, Ont.—The Hoyt Metal Co., will build an addition to its factory on Eastern Avenue.

Prince Rupert, B.C.—It is proposed to establish a new cold storage plant here to aid the fishing industry.

Estevan, Sask.—The C. P. R. is installing a gas producer plant and a 30-h.p. Canadian Fairbanks-Morse Co.'s gas engine in their pumping station here.

Collingwood, Ont.—Electric transmission lines are being installed to carry increased power to the Wm. Kennedy Co's. plant and the electric furnaces will be in operation shortly.

Moose Jaw, Alta.—George Harrison, managing director of the Saskatchewan Bridge & Iron Co., of this town, has invented and built a gas producing plant for burning straw as fuel.

Newcastle, N.B.—The International Shipbuilding Corporation which is erecting shipyards at Newcastle, N.B., has taken over the plant and business of the Sydney Foundry Co., Sydney, N.S.

Niagara Falls, Ont.—The Norton Co. will build this year another unit to their plant at Chippewa for making abrasives. They have installed a waterworks system recently with a mechanical filtration plant.

Owen Sound, Ont.—The Union Cement Co., which has been recently incorporated with a capital of $1,000,000 propose making extensive alterations to their plant and installing new machinery and equipment.

Belleville, Ont.—The buildings in connection with the Cordova Mine in Marmora Township, which were recently destroyed by fire entailing a heavy loss, are being reconstructed. A new process for the treating of ore is also being installed.

Beeton, Ont. — The Hydro-Electric Commission is at present considering the advisability of bringing power from Big Chute to Cookstown, thence to Alliston. There would probably be a sub-station at Nicolston, from which a line would be run to Beeton and Tottenham. Bradford will probably obtain power from the same source.

Niagara Falls, Ont.—Forty miles of steam railway will be laid in connection with the construction of the seven mile canal which will be dug to carry water from Chippawa Creek to the Hydro Electric power Commission's proposed new power plant at Smeaton's Grove near Queenston. The purchase of the right of way for the canal has been completed. Such lands as are not needed for canal purposes will be re-sold for industrial sites. The estimated cost of the canal is $9,000,000; of the power house, $6,000,000.

BUILDING

Toronto, Ont.—A building permit has been issued by the City Architect for a bank and office building at the corner of St. Clair Avenue and Vaughan Road to cost $34,000. The Bank of Commerce will establish a branch in the building.

Hamilton, Ont.—The ratepayers of the Homedale district of Barton Township have passed a resolution to request the township council to issue debentures for $27,000 to pay for the cost of building a four-room addition to Fairfield School.

Montreal, Que.—On the recommendation of the Works Committee, the Catholic School Commission decided to build an additional storey to St. Philomene School, in Rosemount. The cost will amount to about $30,000, and Architects Vautrin and Bernier were instructed to draw the plans accordingly.

Montreal, Que.—At a meeting of the Catholic School Board, J. A. Durocher was awarded the contract for the building of the Lasalle Academy, for the sum of $165,150. The tender of Ulric Boileau offering to build St. Mark's School for the sum of $140,000 was accepted. This school will be of concrete.

MUNICIPAL

Montreal, Que.—One of the aqueduct projects provides for the construction and operation of a munificial artificial ice plant.

St. Genevieve de Batiscan, Que.—The Town Council will install a pumping plant to cost $9,000, and is calling for tenders. Tenerede Trudel is clerk.

St. Catherines, Ont.—Three by-laws will be submitted for the approval of the ratepayers on June 25, to aid by way of a bonus and partial exemption from taxes the following concerns. The Bonner-Heddle Co., St. Catherine Brass Works and St. Catherines Silk Mills.

Winnipeg, Man.—Anticipated revenue and receipts for the city's hydro-electric system for the fiscal year 1917-1918, placed the estimated revenue at $1,050,000 and the expenditure at $980,179.98. The profit estimated is therefore $70,000. The present surplus of $173,348.71 will go towards extensions now being made at Point du Bois, the contract for which is $185,000.

Montreal, Que.—A. Pion the contractor who undertook to complete the contract for the Lasalle bridge for $260,000 has notified the Board of Control that he was usable to carry on the work as he could not furnish the security for the steel work. Mr. Pion told the Board he would be quite willing to contract to do the work for the city on a commission basis of 10 per cent. of what it would cost, the city to furnish security for the steel.

Windsor, Ont.—By a vote of 214 to 7, ratepayers of Ford last Saturday approved of a by-law to grant tax exemptions to the Chalmers Motor Car Co., in return for which this concern will erect a factory in the town. This is the first industrial by-law voted on in Ford since it was incorporated as a separate municipality six years ago. The Chalmers Co. will be exempt from paying taxes, other than school and local improvements, for ten years. The factory was destroyed by fire about two months ago.

Montreal, Que.—After a conference with the consulting engineers, Messrs. Vautelet, McRae, & St. Laurent, the Board of Control resolved to instruct the chief engineer to prepare plans showing the modifications required according to the engineers in projects 2, 4 and 5 of the aqueduct. It was further resolved by the board to instruct the chief engineer to prepare specifications for the supply of electricity for pumping purposes. The board also decided to get comparative information on buying electric power for pumping by hydraulic power, with the present project modified, as suggested by the said engineers.

PERSONAL

William Dott, Liverpool, manager for the Allan Line Steamship Co., died there on June 2.

R. W. Knight has severed his connection with the Standard Steel Construction Co., Welland, Ont., and will shortly return to the United States.

Horace N. Dorling has resigned from his position of inspector for the Imperial Munitions Board to join the sales staff of the Albany Pump Co., Toronto.

H. C. Herpel engineer for the Page-Hersey Iron, Tube & Land Co., Welland, Ont., recently went to Cohoes, N.Y., where the company has purchased the Cohoes Rolling Mills.

W. R. Burge, who recently resigned as Toronto manager of the Jenckes Machine Co., is now a member of the Ontario sales organization of the Canadian Allis-Chalmers, Ltd., Toronto.

Capt. Joseph A. Tymon, one of the best known of inland water sailors, and for many years commander of a Toronto Ferry Co. steamer, passed away on June 5 at his residence, 227 Logan Avenue. Toronto. aged 50.

H. Victor Brayley, has resumed his connection with Gunn, Richards, Ltd., of Montreal and New York, and will be

Aikenhead's NEW CHUCK

After All—

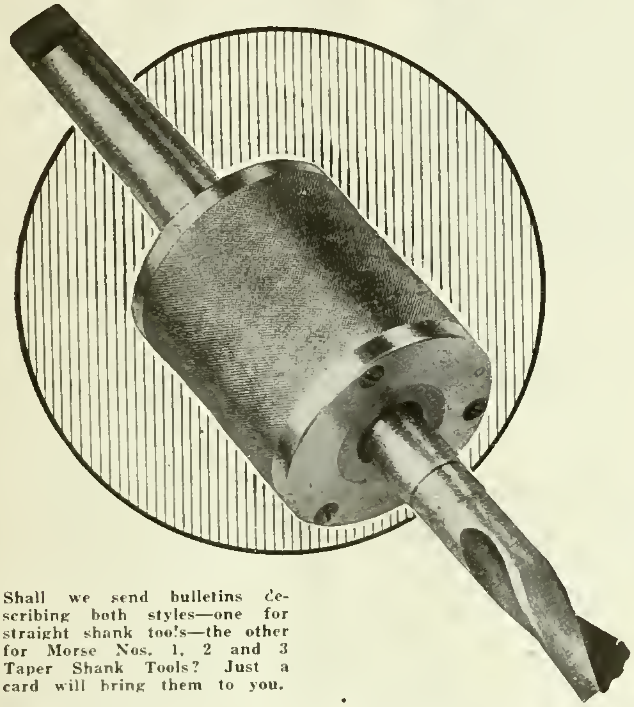
It's production that counts—and it's the simplifying or eliminating of every unnecessary step in every operation that makes for multiplied production. We have told you in their own words—how such representative firms as Pierce-Arrow, Cleveland Automatic Machine Co., and others have boosted their output in drilling, reaming, counterboring and tapping operations in a big way by using

Wahlstrom Automatic Chucks

(They reduce every unnecessary step in drilling operation—no collets—no keys—tool changes made without stopping spindle)

But—no matter how much we tell you about the time-saving possibilities of these chucks—you will never know what they will do in your shop until you've tried them out yourself.

We have a demonstration offer that you should investigate—you can put the Wahlstrom to any test you desire for ten days—if it doesn't perform every operation better and quicker than any chuck in your shop return it to us at our expense.



Shall we send bulletins describing both styles—one for straight shank tools—the other for Morse Nos. 1, 2 and 3 Taper Shank Tools? Just a card will bring them to you.

AIKENHEAD HARDWARE LTD.
17, 19, 21 Temperance St. Toronto, Canada

Aikenhead's M-6 Shell Machine

for cleaning out insides of 4.5 inch Howitzer and 6-inch shells and for retouching rough spots.

This machine has been used with immediate success in a number of large shell factories in Canada. A 14½" special spindle is supplied for 4.5 shell work and a 20" spindle is used on 6" shell work. Specially adapted for cleaning the base of shells *inside*.

The Strand flexible shaft has a *metal casing* that will outwear any other now on the market and adds life to the shaft.

Does away with the trouble common to other flexible shafts. Freely flexible to a certain radius, where it automatically forms a stop, thus preventing accidental short bends.

For full particulars write

AIKENHEAD HARDWARE LIMITED

17, 19, 21 TEMPERANCE STREET, TORONTO

joint Canadian manager with T. Max Fyshe, Mr. Brayley resigned from Gunn, Richards, Ltd., a couple years ago.

E. P. Brady has been appointed general manager of Canadian Government Railways west of the St. Lawrence, and his headquarters will be at Cochrane, Ont. **W. A. Cowan** has been appointed as his assistant. **C. A. Hayes** will be manager of the Government railways east of the St. Lawrence River, which includes the Intercolonial Railway and its branch lines, and also the Prince Edward Island Railway.

Howard G. Kelley, has been appointed acting president of the Grand Trunk Railway in place of **E. J. Chamberlin** who has been granted three months leave of absence. Mr. Kelley was born in Philadelphia, Pa., in 1858. He came to the G. T. R. system as chief engineer, 1907-1911, and since 1911 he has been vice-president of that railway. He was president of the American Railway Engineering and Maintenance of Railway Associations in 1905 and 1906.

Sir George J. Bury, vice-president and general manager of the C. P. R., who is created a Knight, was born in Montreal in 1866, and his promotion has been rapid. At the age of twenty-one he entered the employ of the Canadian Pacific as a clerk in the office of the purchasing department. In 1894, Mr. Bury was made general superintendent of the central division of the road, with headquarters at Winnipeg, and in 1908 he became general manager of the Western lines. In 1911 he was appointed to succeed Sir William Whyte as vice-president and manager of the company's Western lines, with headquarters at Winnipeg. Two years ago he was appointed vice-president at headquarters, Montreal, and general manager of the system.

TRADE GOSSIP

Elmira, Ont.—The Elmira Transmission Co., propose building a foundry.

Toronto, Ont.—The Consumers Gas Co., will build an extension to their plant.

New Toronto, Ont.—Brown's Copper & Brass Rolling Mills, Ltd., have increased their capital stock to $5,000,000.

Bracebridge, Ont. — The Muskoka Foundry Co., has purchased linen mill property, and will be in the market for machinery, new tools, motive and shafting, etc.

Toronto, Ont.—The Swift Canadian Co., are extending their packing house at West Toronto. The Sherwood Construction Co., of Toronto are the general contractors.

The Turbine Equipment Co., Toronto, have sold to the Midwest Refining Co., two-De Laval combination steam turbine driven boiler feed pumps, suitable for 3000 boiler h.p.

St. John, N.B.—The Power House and laundry will be built in connection with the General Hospital here. Complete equipment is required. F. Neil Brodie of St. John is the architect.

Gravenhurst, Ont.—The National Potash Corporation have now begun operations at their plant at Gravenhurst, Ont., with a battery of blast furnaces capable of reducing 200 tons of feldspar per hour.

No Coal From Alberta.—The Alberta Government has decided to insist that no fuel be shipped out of the province until the industries and citizens are equipped for the winter. This means that British Columbia, Saskatchewan and Manitoba cannot secure coal from these mines.

U.S. Steel Tonnage.—The unfilled tonnage of the United States Steel Corporation on May 31 was 11,886,591 tons, according to the report issued a few days ago, a decrease of 296,492 tons from the April 30 figures, which were the highest in the history of the corporation.

Thetford, Que.—The Regent Asbestos Corporation, which owns close to 400 acres in the asbestos district of Thetford, will resume operations owing to the improvement in the market. Orders have been given to have the pit pumped out immediately.

Hamilton, Ont.—The Steel Company of Canada have purchased the steel mill at Morrisburg, Ont., and propose removing the entire plant to Hamilton, if the city will sell some property adjoining the company's works. The Board of Control have the matter under consideration.

Allocate Pig Iron.—The American Iron and Steel Institute has been asked by the Department of Commerce, Washington to name a committee to allocate pig iron in the United States. The British Government has assured the United States that its shippers will observe any regulation by such a committee.

The Turbine Equipment Co., Toronto, have been awarded a contract by the Imperial Oil Co., Ltd., Sarnia, Ont., for two-De Laval 14 in. single stage centrifugal pumps, each having a capacity of 9 million gals. a day against 108 ft., total head. Each of them will be direct connected to Canadian Westinghouse 225 h.p. motors.

Large Copper Output.—In the first four months of this year the principal copper mines of North and South America produced a total approximating 715,000,000 pounds. Of the 715,000,000 pounds produced to date in 1917, Anaconda was responsible for nearly 114,000,000 pounds, with Phelps-Dodge Corporation properties second with a total of 64,000,000 pounds.

The International Malleable Iron Co., Guelph, Ont., have about completed an addition to their factory 216 x 100 feet, which will shortly be in operation. Another extension 90 x 60 feet is being built. New smelting furnaces and annealing ovens when installed will increase the output by 50 per cent. or 3000 tons per year. The satisfactory increase in demand for the company's product has made these extensions necessary.

Will Appoint Fuel Commission.—It is understood that the Dominion Government will shortly appoint a fuel commission which will be given power to take over and operate the mines in the West now tied up with a strike. This will be done as a war measure, and follows the failure to effect a settlement of the difficulty.

Canal Traffic Light.—The statistical report of lake commerce through the canals at Sault Ste. Marie, Michigan and Ontario, for the month of May, 1917, show a large decrease over last year. This showing was due to the almost unprecedented ice conditions over the Great Lakes. The largest decrease is shown in iron ore, of which 5,436,467 tons were locked through, compared with 15,837,114 tons in May, 1916. Grain and wheat show a slight increase, all other items showing decreases.

Sidney, N.S.—Work has commenced on the $3,000,000 coke oven plant for the Dominion Iron & Steel Co. for which the H. Koppers Co., of Pittsburg, Pa., are the general contractors. The plant, which will consist of 120 ovens, will take from eighteen months to two years to complete, but it is expected that the first oven will be ready for use about March, 1918. The construction will be supervised by experts of the By-Products Coke Co. of Canada, Ltd.

F. N. McClean & Sons, consulting and mechanical engineers, have equipped the top floor of the Review Building at Niagara Falls, Ont., with machinery for the manufacture of wire forming and other special automatic machines, and for the manufacture of jigs, dies, etc. Mr. McClean was formerly mechanical spperintendent of the Dominion Chain Co., at Niagara Falls and also of the McKinnon Dash Co's. plant at St. Catherines.

Belleville, Ont.—The Town Council have awarded the following contracts to the Turbine Equipment Co. of Toronto. One-De Laval 6 in. 2-stage centrifugal pump, direct connected to a 150 h.p. motor, having a capacity of 225 million gals. a day against 250 ft. total head. Two-De Laval 6 in. 2-stage pumps. One to have a capacity of 1¾ million gals. a day against 250 ft. total head, and to be direct connected to 125 h.p. motor, and the other to have a capacity of 1,100,000 gals. a day, and to be direct connected to 100 h.p. motor.

Oppose Increase in Freight Rates.—Strong opposition to the application of the railway companies that the Dominion Railway Commission recommend the passage of an order in Council to advance all passenger and freight rates fifteen per cent. as a war measure was made before the Commission at its session in the Provincial House, Vancouver, B.C. The opposition came from members of the Vancouver Board of Trade and representatives of the large industries, who also opposed the proposed increase in the rail and water rates from Eastern and Western Canada.

Nickel Refinery Soon to Open.—Ambrose Monell, president of the International Nickel Co., in the annual report, says that construction of the new refinery at Port Colborne, Ont., is proceeding at a rapid pace, in view of the difficulties in securing labor and materials, and it is expected that the plant will be in operation at the beginning of 1918. This property is located at the Lake Erie entrance of the Welland Canal. The cost of the refinery when completed is expected to be $5,000,000. Up to the close of the fiscal year the actual expenditure on construction had been $1,046,740.

Detachable Engines Replace Canal Horses.—The first stage of a striking experiment in inland water transport was completed with the arrival in London, England, the other day of two barges laden with coal from collieries in the north of England. The barges were propelled for 160 miles by a detachable motor. The new device consists of a four-cylinder, 17 horsepower marine engine, capable of hauling two boats with a load of 100 tons. It is mounted on the top of the cabin, and controlled from the helm. Petrol is employed for starting, and paraffin when running. The engine and attachments can be transhipped from one barge to another in a few minutes, and it is stated that its use means economy in time and money by comparison with towing by horses.

Winter Port Business at St. John, N.B.—During the winter season just ended the exports handled by the C.P.R. at West. St. John aggregated a total of 1,111,957 tons, an increase of 200,582 tons over the previous winter's total. The C.P.R. grain shipments for the winter were 9,000,000 bushels in round numbers; last year they were 13 000,000 bushels. The total of imports handled by the C.P.R. in 1916-17 amounted to 84,629 tons, an increase over last year of 19,312 tons. In addition to the traffic above mentioned, there were large shipments of exports and imports on the East Side which will swell the total of the port's business up to a very large amount. It is estimated that slightly over $1,000.000 were paid out in wages of chekers and longshoremen during the winter.

Large Contracts for Railway Equipment.—It is estimated that the total contract prices for railroad equipment placed with the mills and shops in the United States since the first of January have aggregated $321,200,000, of which $143,000.000 is for cars, $125,200,000 for locomotives, $50,000,000 for rails, and the balance for bridges, terminal work and for track supplies. The making of this equipment has caused a draft upon the steel mills for 2,518,000 tons of steel. Of this total 1,113,000 tons will be rolled into rails, 718,000 tons into bars, plates and shapes for cars, 500.000 tons into forgings, castings and rolled shapes for locomotives, and the balance into structural shapes for bridges and into various forms for track supplies. During the corresponding period last year similar orders called for 4,000,000 tons of steel products, of which 2,733,000 tons were for rails. Aside from rails, 1,271,000 tons went into the manufacture of cars, motive power, bridges and track supplies. Rail contracts since January 1, this year, have been less than one-half of the orders placed in the first five months of 1916, but the 1,404,000 tonnage that went into other equipment this year was 110,000 tons greater than was needed in 1916.

TENDERS

Swift Current, Sask.—Tenders will be received until June 19, by the City of Swift Current, for one Motor-Driven Centrifugal Pump having a capacity of 800 Imperial gallons per minute against a 300 ft. head. Geo. D. Arnott, City Clerk.

Toronto, Ont.—Tenders addressed to the Secretary-Treasurer of the Board of Education, will be received until June 14, for midsummer repairs sundry schools, in the following trades:—Steamfitting, electrical work, ash hoists, etc. Specifications may be seen and all information obtained at the office of the Superintendent of Buildings. Administration building, 155 College St.

INCORPORATIONS

The McTavish Motor Co., of Calgary, Alta., has been incorporated with a capital of $20,000.

Winnipeg, Man.—The Waterloo Boy Kerosene Tractor of Canada, has been incorporated with a capital stock of $20,000 by W. F. Rondabush, C. A. Sargent, E. P. Hayden and others to manufacture tractors, form implements, tools, etc.

Beaverton Toy Co. has been incorporated at Toronto with a capital of $40,000 to manufacture toys, etc., at Beverton, Ont. The provisional directors are B. Madill, Mr. Shapiro and A. Cooperman all of Beaverton, Ont.

Waterbury Chemical Co. of Canada, Ltd., has been incorporated at Toronto, with a capital of $125,000 to manufacture chemicals and drugs etc., of all kinds at Toronto. The provisional directors are J. R. O'Connor, Allan A. Bain and L. A. Bayes all of Toronto.

Hudson Bay Knitting Co., has been incorporated at Ottawa with a capital of $500,000 to manufacture cotton, woolen and linen goods, etc., of all kinds. Head office is at Montreal and the incorporators are T. B. Gould, F. P. Brais and A. Savard all of Montreal.

Fabri-Cord Tire Co., of Canada, Ltd., has been incorporated at Ottawa with a capital of $1,500,000 to manufacture rubber and gutta-percha goods of all kinds. Head office is at Toronto and the incorporators are A. L. Reid, K. D. Mackenzie and A. MacBorthwick, all of Toronto.

The Foundation Co., of British Columbia, Ltd., has been incorporated at Ottawa with a capital of $30,000 to carry on a construction business. The head office is at Montreal and the incorporators are G. W. MacDougall, W. B. Scott and J. Macnaughton all of Montreal.

Ker Woodturning Co., has been incorporated at Toronto with a capital of $40,000 to carry on the business of woodturning and operating in woods of all kinds. The head office is in Toronto and the provisional directors are Thomas Ker, G. H. Harper and W. J. McWaters all of Toronto .

WOODWORKING

Victoria, B.C.—Damage estimated at about $100,000 was done in a fire which broke out on June 8 at the Cameron Lumber Co's. mills near Selkirk Water. The planing mill, box factory and cross-arm factory, together with the greater part of the machine shop are included in the damage done by the outbreak, which is traced to a hot journal-box in one of the machines. A small insurance was carried.

RAILWAYS—BRIDGES

Vancouver, B.C.—The new Great Northern and Canadian Northern Pacific union depot was thrown open to the public on June 2.

Stratford, Ont.—The Bridges and Roads Committee of the Perth County Council has recommended that all the county bridges out of order be repaired

Simcoe, Ont.—A deputation from Port Dover asked the County Council for the rebuilding of the swinging bridge over the mouth of the Lynn River there.

Winnipeg, Man.—In a few weeks a start will be made on the construction of the new 700-foot bridge to be built over the Red river connecting Winnipeg with St. Boniface from the foot of Provencher avenue. The Dominion Bridge Co. has the contract to "deliver a completed bridge for $241,000," with two piers that will hold the machinery for the movable spans, and which will have to be raised six feet above their present level. The cost of the structure is being borne jointly by the city of Winnipeg and St. Boniface, the city of Winnipeg to provide the electric power for the spans, machinery and lighting.

CONTRACTS

Oshawa, Ont.—The Town Council have acepted the tender of the John Ver Mehr Engineering Co., of Toronto, for the installation of a filtration plant.

Sudbury, Ont.—The Town Council has awarded a contract for a standpipe to the Chicago Bridge & Iron Co., of Bridgeburg, Ont., for $31,065.

Oshawa, Ont.—The Town Council have awarded a contract to the Turbine Equipment Co., Toronto, for one 6-inch 2 stage, De Laval centrifugal pump, to have 1½ million gals. a day against 340 ft. total head, and to be direct connected to 150 h.p. motor.

MARINE

The Halifax Shipbuilding Co., with a capital stock of three million dollars and head offices at Halifax, N.S., has been Federally incorporated. The provisional directors are given as members of a Halifax law firm.

Halifax, N.S.—The Canadian steamer Premier, while coming out of Sambro, in a fog, on June 4, went ashore on Pollock Ledges, and is still hard and fast aground. The crew was taken off by steamers that went to her assistance. The vessel registered 275 tons, and was formerly owned in Toronto.

New Glasgow, N.S.—The first steamer to be built by the Novt Scotia Steel & Coal Co., will be ready to launch in three or four weeks. Work on the second steamer, which is 25 per cent. larger than the first, is well advanced, and as soon as the first is launched the keel of a third will be laid.

Carried Record Cargo.—When the steamer W. Grant Morden left Port Arthur, early this month, she carried the largest cargo of oats which has left the head of the lakes. There were 765,000 bushels of oats in her holds. The Morden is the largest freighter on the lakes, and was built at the Port Arthur shipbuilding plant.

St. Catharines, Ont.—A rather rare event occurred on June 7, when the steamer Schuylkill, which for a number of years has been engaged in freight service on the Great Lakes, passed through the Welland Canal in two parts. She was cut in two sections in a Buffalo dry dock, and will again be joined in Quebec prior to going into service on the Atlantic.

Anchor, Donaldson, Ltd.—In connection with the recent formation of Anchor, Donaldson, Ltd., announced in the Lloyd's list, the Donaldson Line management explain that the new company has acquired the steamers Letitia, Saturnia, Cassandra and Athenia. Otherwise the Donaldson Line continues as before, managed by the Donaldson Brothers, Ltd., and there is no prospect of further change.

Schooner "McClure" Torpedoed.—Private advices announce that the three-masted schooner McClure, formerly owned and sailed by Captain Isaac A. Hopkins, of Halifax, has been torpedoed in the Mediterranean. Captain Augustus Taylor and crew are safe. The McClure was sold by Captain Hopkins to G. A. Taylor, of St. John's, Nfld., and Capt. Taylor and crew came to Halifax last winter and took the vessel to St. John's with a general cargo. On this trip the McClure had a cargo of fish from St. John's. She was a vessel of 191 tons register.

Lakes All Higher in May.—Each of the Great Lakes attained a higher level in May than in April, and with the exception of Lake Ontario, each was above the average for the month in the past ten years, according to the monthly report issued by the United States Lake Survey Office at Detroit, Mich., on June 7. The stages of each of the lakes in feet above mean sea level in May, as compared with April, were:—

	April.	May.
Superior	602.28	602.38
Michigan-Huron	580.78	581.14
St. Clair	575.21	576.07
Erie	572.57	572.93
Ontario	246.24	246.51

FOR SALE

FOR SALE — 1 HOLDEN-MORGAN BASE milling machine, 3-inch shell. Manitoba Bridge & Iron Works, Winnipeg.

FOR SALE—ONE LEWIS TYPE ENGINE built by Waterous Engine Works, 240 H.P., flywheel 73" x 18", automatic governor, a bargain. One steam pump, 4½" x 2¾" x 4". Write Box 217, Moncton, N.B. c24m

ONE—50 K.W., 220 VOLT, D.C. PEERLESS Self-oiling, Automatic Engine, with Switchboard complete. Two, 10 H.P., D.C., 220 volts motor; one 20 H.P., D.C., 220 volts motor; one feed-water heater and purifier 36" x 12'.—The American Motor Sales, Chatham, Ont. c24m

TWO NEW BOILERS, 66" x 16', FOR SALE, immediate shipment. One smoke stack, 54" x 80', also one C.G.E. generator, 62.5 K.V.A. with exciter and switchboard. Box 312, Canadian Machinery. (c24m)

ONE LATHE 16" x 4½' BACK-GEARED — Built by P. P. Silk Machine & Tool Co., Cincinnati, Ohio. One lathe 18" x 3', back-geared. Built by the Bradford Mill Co., Cincinnati, Ohio. Four Murchey collapsible dies. Capacity 1½" to 2½". Box 272, Canadian Machinery. ctmf

FOR SALE—TWO 16 x 6 REED PRENTICE Automatic Lathes. One Bertram Gap Lathe, 48 x 10. Four No. 10 Heavy Duty Baker Drills. One No. 2D Colburne Drill. One Heavy Duty Reliance Machine Co. Turret Lathe for inside boring of 6" shells. Canadian Blower & Forge Co., Kitchener, Ont. c24m

WE HAVE ON HAND AT OUR WELLAND Works, for disposal, the following new machinery:—One (1) 18" x 15 ft. Accumulator; one (1) Aldrich Triplex Hydraulic Pump, 180 gals. capacity; two (2) 350-ton B. and B. Presses. All offers will be carefully considered. Canadian Car & Foundry Co., Ltd., Transportation Building, Montreal.

THE NATIONAL MANUFACTURING COMPany, Limited, Ottawa, have the following machine tools for sale:—1 25-ft. Westinghouse Air Compressor, with Receiver; 1 20" Drill Press; 1 4-spindle 12" Drill Press, Cincinnati Pulley & Machine Co.; 1 Canadian Blower & Forge Co., 21" Drill Press; 2 Racine Power Hack Saws; 1 McKechnie Bertram Planer, 36" x 36" x 10' 0" bed; 1 Wagner Motor, 10 H.P., 2-Phase, 60 Cycles, 440 Volts, 1140 R.P.M., complete with starting base; 1 Barnes 21" Drill Press; 5 Simplex Lathes, never used; 2 Ford-Smith Grinders, suitable for 18-pdr. Shrapnel Shell; 2 Thread Millers for 18-pdr. Shrapnel, in need of repairs; 3 Shrapnel Furnaces; 1 Turret Lathe. c23m

1—ROBB HORIZONTAL STEAM ENGINE, 10 x 12, 35 h.p. Just overhauled by makers. Price $300.00. 1 Heavy Duty Rockford Drill. Suitable for shells or heavy work. Weight of drill 3,600 lbs. Good as new. Write for specification. 1—Jones & Lamson 2 x 24 Turret Lathe, 2¼" hole in spindle, 16" swing, cone drive, collet chucks for bars up to 2" diameter. Or lathe can be fitted with standard universal chuck. Flat turret 16" diameter. Good condition. Price $400.00. 1—Warner & Swasey Turret Lathe. Round turret, diameter 8", hand cross feed for turret. Swing 14". Fairly good condition. Price $200.00. 1—Bertram 2-spindle Thread Miller. Made by makers for threading 18-pdr. shells. Now used for threading sockets. Good condition. Steel Furnishing Co., Ltd., New Glasgow, Nova Scotia. c2m

BUSINESS CHANCES

SHELL PLANT FOR SALE — COMPLETE plant installed since 1914, for the machining and assembling of 4.5 inch H.E. shells, situated at Dartmouth, Nova Scotia, on line of Intercolonial Railway, with siding running into the works. Will sell the equipment outright, with privilege of renting the building in event of the purchaser engaging in the same business. Starr Manufacturing Co., Limited, Dartmouth, Nova Scotia, Canada. c26m

FOR SALE—A MEDIUM-SIZED TWO-STOREY brick factory situated in the best small city in Ontario. Buildings in good condition, suitable for either metal or wood-working; shipping facilities unexcelled. Two trunk lines; direct connections east, west, north and south. Educational advantages the very best. Plant will be sold at a bargain and on easy terms of payment, if desired. Apply Box 294, Canadian Machinery. c2m

AGENCIES WANTED

AGENTS HAVING CONNECTION WITH large workshops factories in mechanical construction business and dealing in tools and tool outputs, wish to represent in France a good house manufacturing especially Lathes, Drills, Files, Vises, Tinware, Machinery, Tool Outputs, etc. Good references. Address Hoon & Barronnet, 11 Rue Bichet, Paris. c24m

SPECIAL MACHINERY

MANUFACTURERS—WE CAN UNDERTAKE work to any specification—munition production equipment or otherwise. Write W. H. Sumbling Machinery Co., 7 St. Mary St., Toronto.

S. VESSOT & CO., GENERAL MACHINE SHOP and Grey Iron Foundry. We can undertake at present time light machining and grey iron castings, at reasonable prices. Address Joliette, Que. c1m

"Moving pretty good, eh?"

After two insertions of their half-column ad on used equipment, three items were cut out. After two more several more were omitted.

No wonder the advertiser said: "Moving pretty good, eh?" And they go on to say: "We feel we have been pretty successful in removing this second-hand equipment so readily." You can do the same. Let an ad in Canadian Machinery help you do it.

SITUATIONS WANTED

HIGH-GRADE MAN, EXPERIENCED IN GENeral construction, manufacturing, machine shop work and heavy shells, is open for a good offer only. Box 315, Canadian Machinery. c25m

PRACTICAL WORKS MANAGER AND MEchanical expert with years of experience in United States and Canada, a specialist in munition work, open for engagement. Best of references. Apply Box 304, Canadian Machinery. c4m

ELECTRICAL ENGINEER—COLLEGE GRADUate, five years' practical experience; now employed in large industrial plant, electric-driven; responsible position desired; money not sole object; recommendations. Box 305, Canadian Machinery. c26m

WANTED — POSITIONS FOR THOROUGH Mechanics, Toolmakers, Toolsetters, Grinders, Borers, Automatic Operators, General Foremen, Chief Munition Inspectors; positions for soldiers deprived of limb, if hands whole, for table work inspecting, etc.; also for female artisans of all kinds, viz., Munition Inspectors, Operators, Superintendents, Timekeepers and Female Elevator attendants tall, age over thirty; matrons. Employers send to "Toronto Engineering Agency," 57 Queen W., Toronto, Adel. 809. c24m

SITUATIONS VACANT

WANTED—TOOL MAKERS TO WORK ON munitions. Apply at once. Wallaceburg Brass & Iron Mfg. Co., Ltd., Wallaceburg, Ontario. c25m

THOROUGHLY CAPABLE BRASS FOUNDRY Foreman to take charge of small foundry doing a general jobbing business and also munition work. Location Montreal. Address for information, "Brass Foreman," P.O. Box 1934, Montreal. c26m

WANTED—TWO EXPERIENCED BORING lathe hands to take charge on day and night shifts, of battery of boring lathes for 6" Mark III. shell. Only men who can get good bores and high production need apply. Give in the first instance, experience, wages required and full particulars, otherwise application will not be considered. Box 317, Canadian Machinery. c26m

HOISTING MACHINERY SALESMAN, BEtween ages of 30 and 40; prefer, if possible, man having experience machine shop, drafting room, general office, as well as actual selling. Man of sound training and good judgment assured steadily increasing salary and good future. Reply, giving all needful information in few words, to Box No. 318, Canadian Machinery. c25m

6" SHELL FOREMAN WANTED WITH SPEcial qualications to get production from shop at Peterborough, Ont., which has been running on 6" shell for eighteen months. Tooling and shop inspection separately organized. Foreman to give his whole attention to obtaining maximum production. Give full particulars in first application as to previous experience, references, and salary required, otherwise application will not be considered. Apply to Box 316, Canadian Machinery. c25m

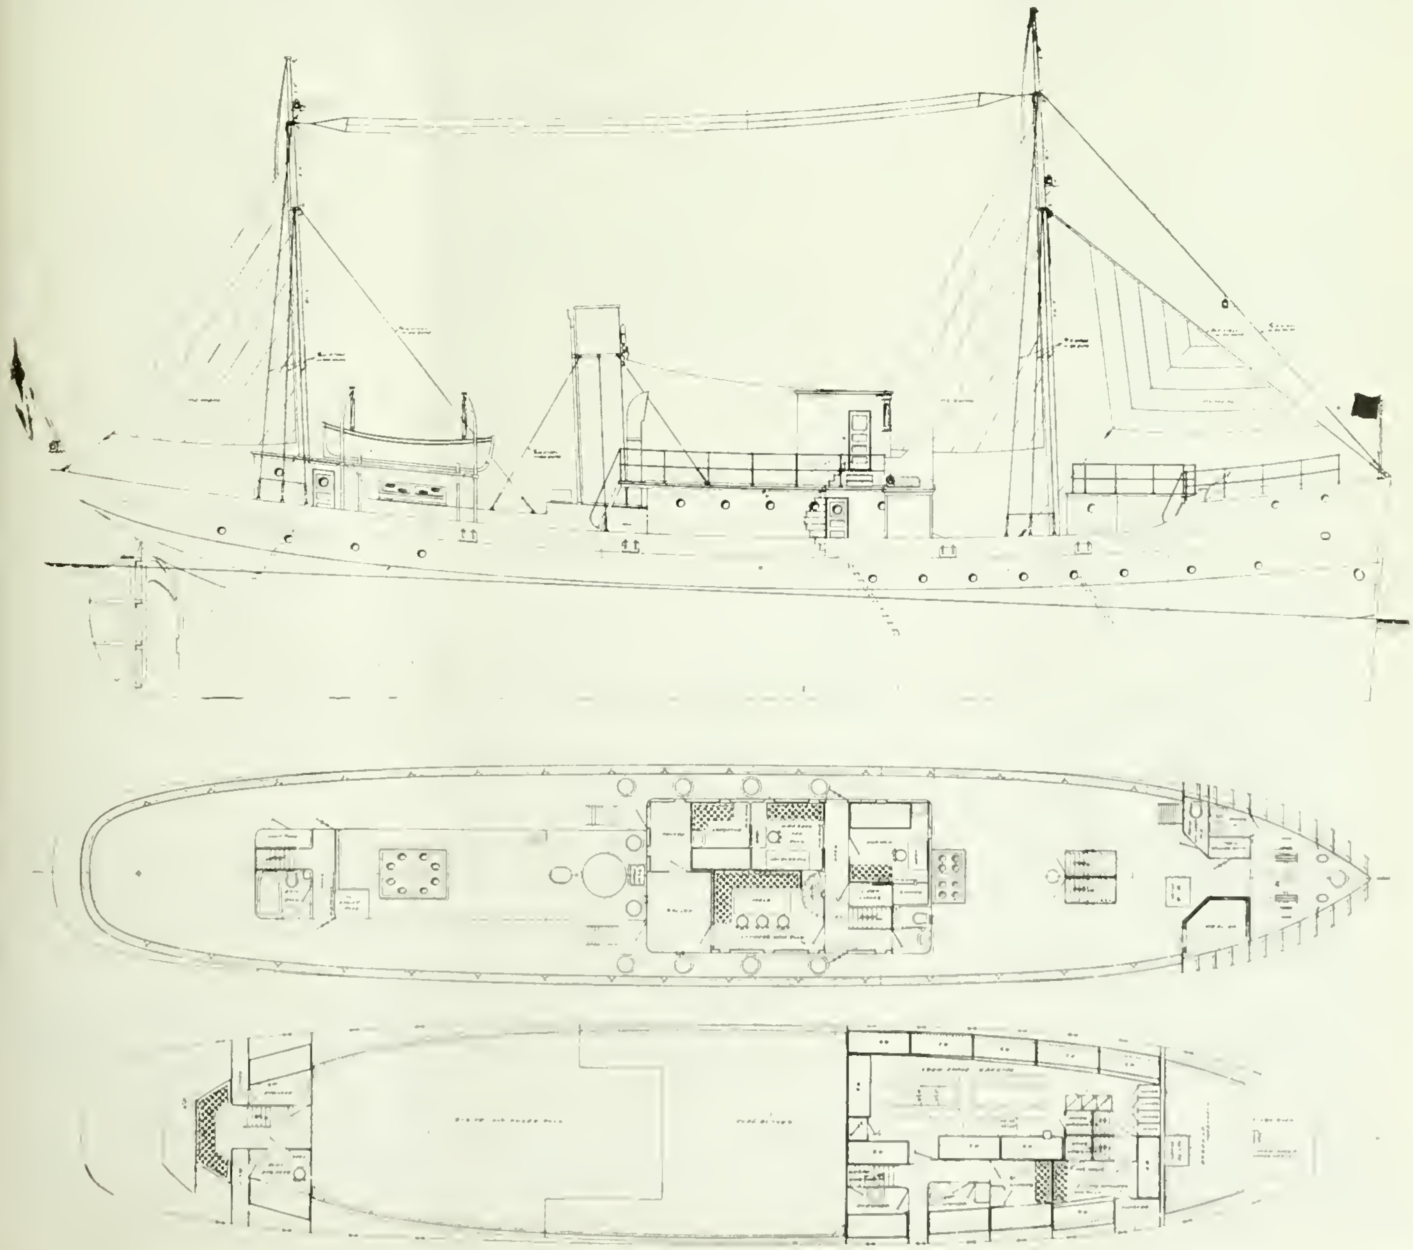
Fisheries Protection Vessels Launched at Toronto

By C.T.R.

Some quite appreciable evidence of the activity which now marks shipbuilding and marine engineering in Canada has been made available by the launch from the Polson Iron Works, Toronto, in one afternoon, of four trim little craft for our fisheries protection service. The choice of names by which each vessel, including two others, will be known—"Ypres," "Messines," "St. Julien," "Vimy," "St. Eloi" and "Festubert," is a happy one, paying as it does a graceful compliment to our soldiers—the dead, the wounded, and the unscathed, all of whom covered themselves with glory in the six named victories over the Germans.

AT intervals of from five to six minutes, beginning promptly at noon, Saturday, June 16, four out of six Canadian Government Fisheries Protection vessels under construction by the Polson Iron Works, Toronto, were released from the ways and transferred successfully to their native element in presence of several thousand spectators. The shipyard was gaily decorated with flags and bunting for the occasion, which was unique, in view of the fact that the quadruple launching is believed to be the first of its kind to take place on this continent, or for that matter anywhere. Tastefully flag-draped stands were erected for the accommodation of the specially invited guests, and from which the christening ceremonies were performed by Mrs. Hugh McKay and Miss Athlea Hazen, daughters of the Hon. J. D. Hazen, Minister of Marine and Fisheries, who was also present. Prominent among the builder's specially invited launching party were to be noted Admiral Kingsmill and J. C. Desbarats, of the Department of Naval Service, Ottawa; Col. Chambers, Chief Press Censor, Ottawa, who had been attending the Canadian Press Association Annual Convention; Mayor Church, H. A. Terrault, superintendent of construction, Ottawa; J. S. Irwin, Ottawa; Holt Gurney, T. A. Russell, R. R. E. Chisholm, Ottawa; Claude Macdonell, M.P.; Sir Frederick Stupart, T. H. Navin, Joseph E. Oliver, Captain James B. Foote, James Somers, George Gouinlock, W. J. McWhinney, K.C., Capt.



ACCOMMODATION AND RIGGING PLANS, FISHERIES PROTECTION VESSELS.

J. J. Manley, Port Arthur; Capt. E. Winstrop and Capt. Resfnes, representing Norwegian shipping interests; Lloyd Harris, Capt. Harry Miller, W. B. Tindall, Arthur Taylor, John Sharpe, Peter Bain, A. Guy Webster, and Geo. E. Pearson, of the MacLean Publishing Co.; Acton Burrows, of the Railway and Marine World, and many ladies. Mrs. McKay and Miss Hazen were each the recipient of a sheaf of roses by the firm.

Rapid Progress Made

Only some twelve weeks have elapsed since the keels of all six of the vessels were laid, and with four of them afloat—"Ypres," "Vimy," "Messines," and "St. Julien," and with the other two—"St. Eloi" and "Festubert," following suit in about fourteen days' time, it will be at once appreciated that the shipyard management, despite labor scarcity and the difficulty of procuring materials of construction promptly, are deserving of the highest commendation for their achievement. Further, when account is taken of the fact that two months of the specified time limit of completion for all six vessels has yet to run, and that the propelling and auxiliary machinery, together with the hull outfit equipment, are ready to instal, it may be readily forecast that every one of the little craft will be on service on dates in every case ahead of requirement.

Guests and Employees Entertained

Following the launching ceremony, a buffet luncheon was served to the invited guests in a large marquee erected within the yard. At the same time refreshments and "smokes" were served to the firm's employees by the management in another section of the plant, a proceeding which was greatly enjoyed and which demonstrates the interest taken by the executive in its employees, and which the latter in turn reciprocate by whole-hearted honest effort.

Hon. J. D. Hazen's Sueech

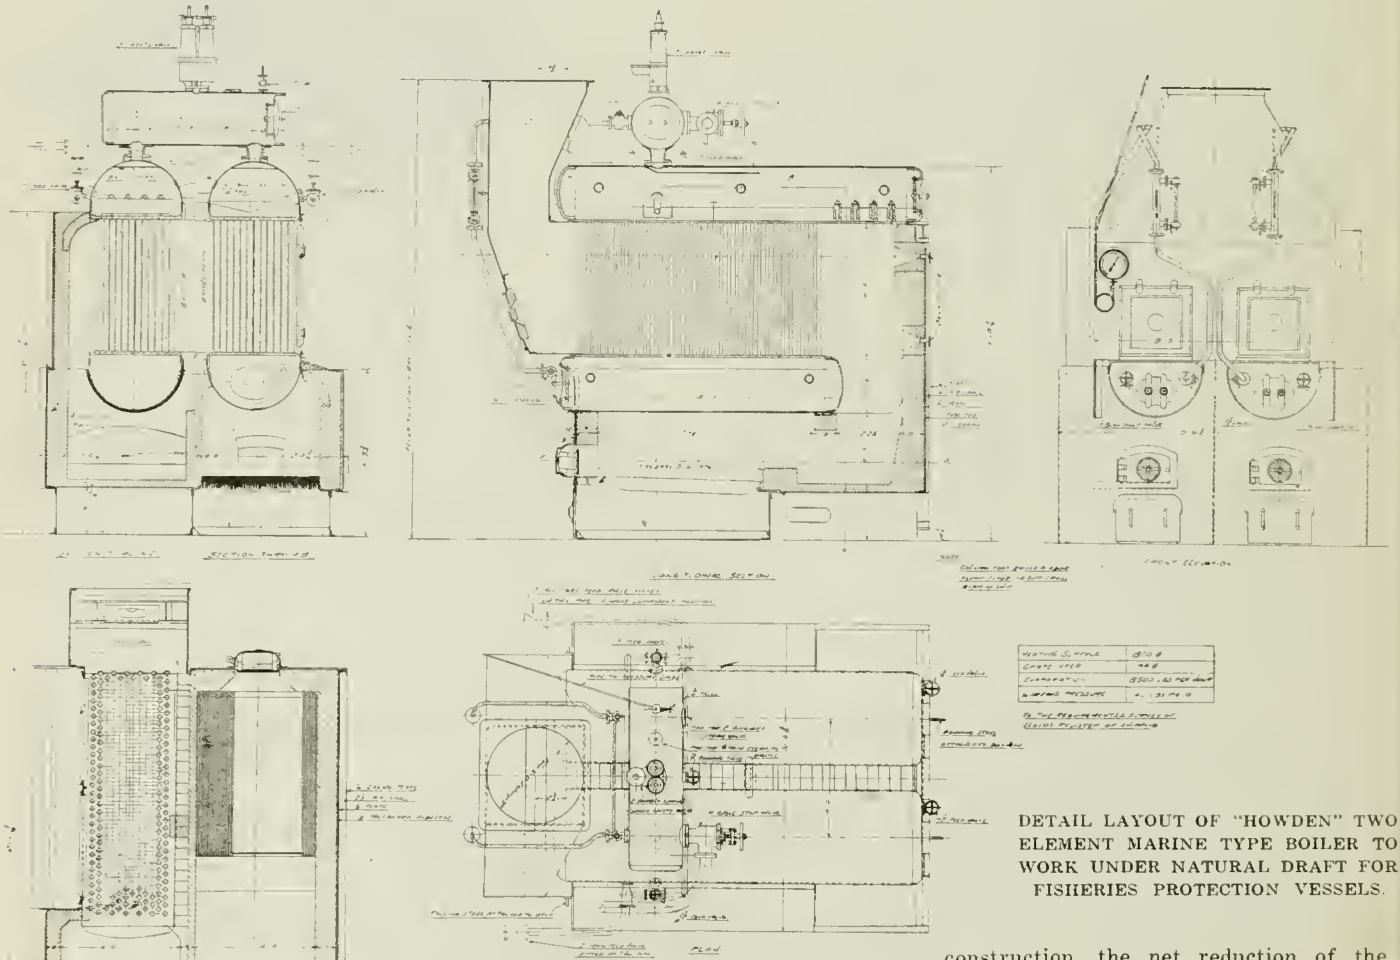
After full justice had been done to the hospitality provided, Col. J. B. Millei, president of the Polson Iron Works, introduced the Hon. Mr. Hazen, who gave a short address on the shipbuilding situation from the executive viewpoint, and from which we quote as follows:—

"The successful termination of the war will depend, to no small extent on the ability of the British Empire and our Allies to maintain sufficient shipping to carry on essential trades. The successes that we have achieved all along since the war commenced are due in no small measure to the efficiency of the British and Allied mercantile fleets.

"Lloyd George has said quite recently that one of the best ways of carrying on the war was by the production of ships and then more ships. Let me remind you that the losses to shipping, as the result of submarines and other enemy agencies, since the commencement of the war have been enormous, even although they have not nearly approximated the boastful expectations and predictions of the Germans. They have, nevertheless, been serious, totalling up to the end of April last about 5,811,100 tons. How stupendous this loss is, you will understand when I point out that the replacement value approximates, if it does not exceed, one thousand million dollars. Notwithstanding these enormous losses, there is the comforting thought that the construction of new ships has during the period of the war been well maintained, more especially by Great Britain and the United States.

Construction Combatting Destruction

"Without entering into any details, I may say that the total of the world's mercantile marine tonnage at the close of 1916 was 48,683,136 tons. Even if it so happens that the present ratio of destruction should be maintained for another year or, say, until the end of June, 1918, if we maintain the present ratio of construction, the net reduction of the world's tonnage would be only about two per cent. Recent reports, however, go to show that there is no probability of the present ratio of destruction being maintained, and I ask your attention for a few moments while I submit a few facts as to what is being done in Canadian shipyards, to say nothing of the tremendous activity in ship construction in



DETAIL LAYOUT OF "HOWDEN" TWO ELEMENT MARINE TYPE BOILER TO WORK UNDER NATURAL DRAFT FOR FISHERIES PROTECTION VESSELS.

Great Britain and the United States and in Japan, to establish that there is conclusive evidence that the ratio of construction will be more than maintained.

"There are at the present time under construction in Canadian shipyards merchant steamers totalling approximately 150,000 tons carrying capacity. The cost of producing this tonnage will be in the vicinity of $25,000,000. In addition, there are building in various Canadian yards wooden vessels aggregating a total carrying capacity of about 30,000 tons."

On the call of Col. Miller, three cheers were given the Minister of Marine and Fisheries for his presence and address. Mr. Hazen, in reply, called for three cheers for Col. Miller, Mr. Newman, the shipyard staff and employees generally, following which on his lead, three cheers and a tiger were given for the King.

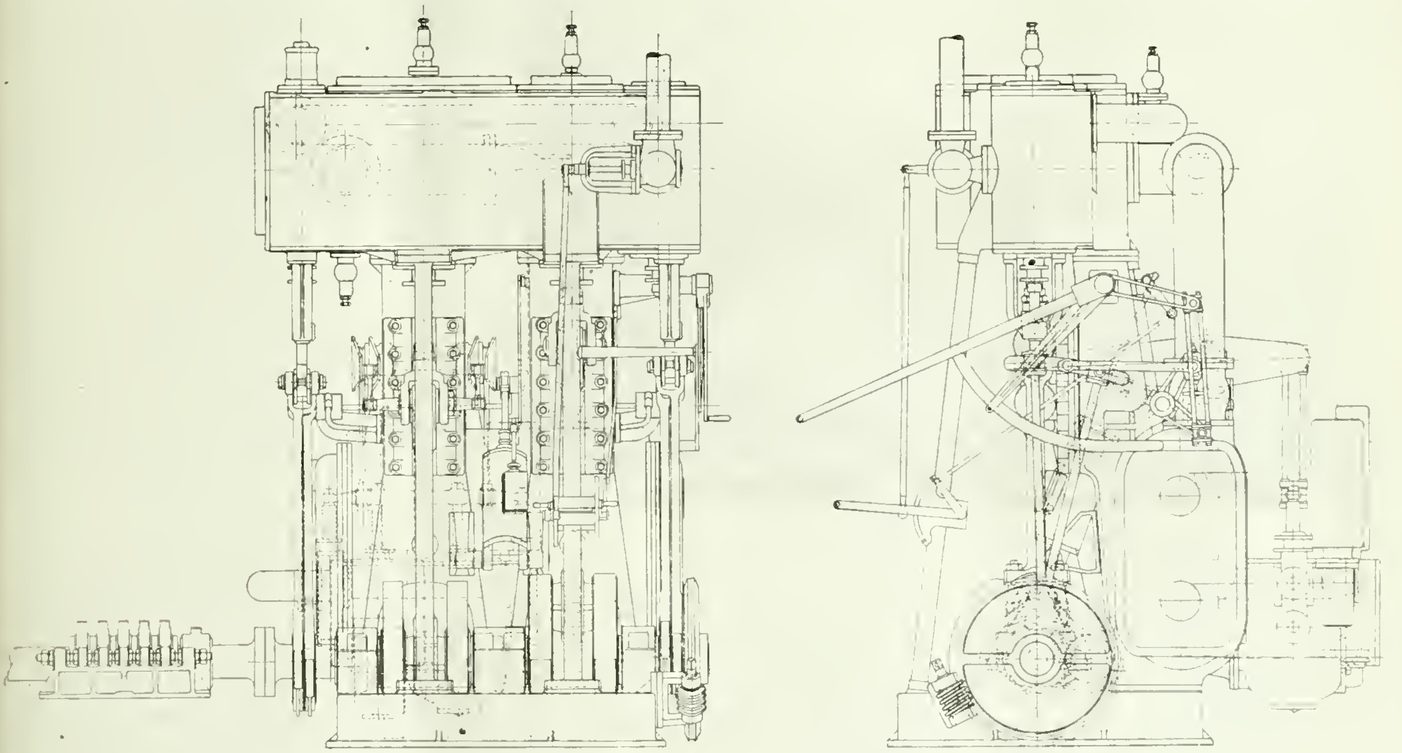
Vessel Features

The vessels are constructed entirely of steel equal to Lloyds' requirements and have the following principal dimensions. Length between perpendiculars 135 feet; breadth extreme 23 feet 6 in.; moulded depth 13 feet 6 in., with deck beam camber of 7 inches. They are built on the deep frame system with ordinary floors throughout and have a straight stem and elliptical stern. The propelling machinery is located aft, the stokehold being at the forward end of the boiler with bunkers adjacent capable of holding 180 tons of coal. The crew's quarters as also their mess room and that for the petty officers are forward there being accomodation for eighteen men. The cabin which is situated on the main deck forward of the smoke stack, has separate state rooms for the captain, chief engineer and first mate while there is also a bathroom and lavatory. On the main deck is located the galley with steward's and cook's room, also the officers' mess room and pantry. Above the cabin, forward, is the "Texas," embracing wheelhouse and chart room, wireless room, with operator's quarters in rear, and bridge oposite to door of the wheel house. Accomodation which includes a bath room for two engineers and second mate, is located aft below the main deck. Access is had from the main deck and also through a bulkhead from the engine room.

Constructional Details

The keel and stem are of mild steel $7\frac{1}{2}$ in. by $1\frac{1}{2}$ in., while the stern post is of cast steel equal to Lloyds requirements. The rudder is of the single plate type, with arms shrunk and keyed on to post, and carrying four portable pintles. The top pintle is fitted with a locking device to prevent rudder from lifting. The frames are of the deep type consisting of 5 x 3 x 3/8 in. angles with compensation in lieu of heel pieces. The floors are of steel plate 16 x 7/20 in. in the hold space, increased in thickness in engine and boiler space and flanged on top where required. The beams of $5\frac{1}{2}$ x 3 x 10/20 in. angle on alternate frames are fitted with bracket knees of ample depth. The centre keelson is formed of channel bar. The main deck stringers are of plate 30 x 7/20 in., amidship, and are connected to shell plating by riveted angles 3 x 3 x 5/20 in.

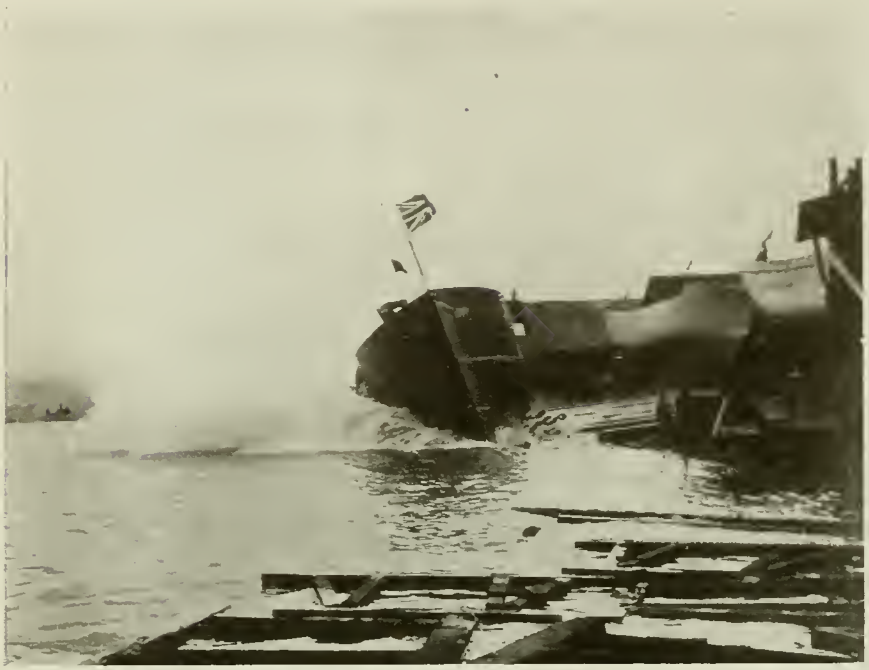
The garboard strake is 9/20 in. thick, the sheer strake 11/20 in., thick, and the remainder of the hull plating 3/8 in. thick amidship. Riveting of shell plating seams is double throughout. The bulwarks are of 5/16 in. thick steel plate, rising 2 ft. 8 in. high above wood deck. Rolling chocks extend for a distance of 45 feet on each side of the vessel and are formed of 7 in. bulb bar, backed by $3\frac{1}{2}$ by 9/20 in. angle. There are four freeing ports on each side fitted with strong hinged doors of the balanced type. Bulkheads are all of watertight construction. The two fresh water tanks are cement washed inside and have filling and air pipes, drain plug and hand pump. The decks are of British Columbia fir as are also the cabin floors, etc. The equipment consists of steam and hand steering gear in the wheelhouse, and a "Dake" steam windless fitted under the turtle deck forward. The foremast is 13 in., and the mizzen mast 11 in. diameter. Each vessel has two Bower and one kedge anchor. A ship's boat of wood is carried fully equipped.



COMPOUND SURFACE CONDENSING ENGINES FOR FISHERIES PROTECTION VESSELS.

Machinery

The propelling machinery consists of a fore and aft compound surface condensing engine having cylinders 18 in. and 38in. in diameter by 24 in. stroke. The high pressure cylinder is fitted with a piston valve and the low pressure with a double ported slide valve. The crank shaft $7\frac{3}{4}$ in. diameter is built up, counterbalance weights being attached to the cast steel webs. The couplings are also of cast steel. A separate thrust shaft with solid forged collars is installed. The surface condenser is cast on the engine back columns and contains 900 square feet of cooling surface. The air pump is of the Edwards type. The circulating pump, feed and bilge pumps are Blake-Knowles type, and are attached to the main engine and driven by levers attached to the low pressure crosshead. The propeller shaft is fitted with bronze sleeves, while the stern-tube is of cast iron with a removable brass bush filled with lignum vitae. The propeller is of cast steel with four blades. A feed water heater is provided.



SHOWING THE "VIMY" TAKING THE PLUNGE.

The main steam piping is of seamless steel tubing with steel flanges, while all other pipes including the exhaust are wrought iron. The main boiler feed and blow off pipes are, however, made of copper.

Boiler Installation

The boiler is of the "Howden" combination sectional marine, two element, type. The total heating surface is 1870 sq. ft., the grate area 44 sq. ft., and the working pressure 180 lbs. per sq. inch. The evaporation available is 9,000 lbs. per hour from a combined heat absorbing surface of 1870 sq. ft., and 44 sq. ft., grate area using coal of not less than 12,000 B.t.u. per lb., and with .75 in. forced draught. There are two top and two bottom drums one set of two drums belonging to each element. Each element has 378 tubes of 2 ins. in diameter by 4 ft. 6 in. long between tube plates. Howden latest and improved type of forced draft equipment is fitted, an air heater being installed on the boiler front. Hot gases from the flues are utilized for this purpose. The drums of each element are connected by equalizing pipes while a steam drum connects the top elements for the main steam pipe connection. The boiler is tested by water pressure to 360 lbs. per sq. inch. The steel frame work supporting the boiler is designed and constructed to allow full freedom for any expansion that may take place.

A general service Blake-Knowles, vertical duplex 8-5-12 in. pump is installed to draw from the sea and fresh water tank, and to discharge to deck service and boiler. The sanitary pump $5\frac{1}{2}$-$3\frac{3}{4}$-5 in. is a horizontal duplex Blake-Knowles unit. Electric lighting for general and searchlight purposes is supplied by a 10 k.w. direct connected steam engine and generator. A complete evaporating outfit is installed having a capacity of 8 tons per day.

MONTREAL INTERESTS ACQUIRE WOOD SHIPBUILDING PLANT

A GROUP of Montreal capitalists, including William Lyall, president of the P. Lyall & Sons' Construction Co.; H. W Beauclerc, a Lyall director, and others of their associates, have acquired the wooden shipbuilding branch of the Wallace Shipbuilding Co.'s business at Vancouver, B.C., and will at once incorporate a new company to carry on the business. The company will have a Dominion charter. The negotiations were recently concluded at Vancouver by Mr. Lyall, who had been at the coast for some time going into the matter. The purchase price has already been paid over. This is a going concern, with a number of vessels now under construction.

Accompanying Mr. Lyall were two representatives of the Imperial Munitions Board, who have satisfied themselves as to the company's ability to build ships, and a contract for several vessels for the British Government has already been closed. These vessels will be of the standardized 3,000-ton type already being built on the coast. They will cost approximately $400,000 each, and the company expects to be able to turn out a number this year. The property purchased from the Wallace Co. includes three shipbuilding slips, and three more will be constructed, so that several vessels may be building simultaneously.

The new company has an experienced staff of experts engaged for the more responsible positions.

SHOWING THE FOUR VESSELS ON THE WAYS PREVIOUS TO LAUNCHING.

PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

SPECIAL CIRCULAR TURNING TOOL

By J. H. R.

WHEN turning the nose profile of the various size shell, difficulty has often been experienced in maintaining a uniform contour on each; this being due more particularly to the variation in the shape of the cutting tool after each grinding or re-setting operation. Owing to the parallel advance of the cutting tool, it is obvious that the working point will gradually change as the tool approaches the small diameter at the nose, and for this reason it is essential that special attention be given to the shape and setting of the tool, so that a uniform profile will be turned on each shell. To eliminate as far as possible, the trouble caused by faulty grinding, the tool shown in the accompanying sketch, was designed by the Modern Tool Mfg. Co., and its efficiency has been demonstrated where it is found necessary to machine work by the cam or radius method.

The details of the tool and holder are shown in Fig. 1; the holder is made of 2½ inch by 1½ inch low carbon steel, the front portion being inclined at an angle and bored and threaded to receive the adjustable stud B. The upper end of this stud is turned to fit the central hole of the circular cutter C, and is drilled and tapped to receive the clamping screw D. The bevel portion on the stud B and also on the head of the bolt D, are the same so as to fit the bevels on either side of the cutter C; this facilitates the setting of the tool and increases its life, as the tool may be reversed without changing its shape or setting. The tool is used on the finish turn operation and can machine quite a number of shells before regrinding is necessary. When the edge becomes dull, the clamping screw is released and the circular tool turned about one-eighth of a revolution, thus giving 16 settings, using both sides, before regrinding is required. After the edges have been ground, however, the height of the cutting edge must be adjusted by raising the stud B to the desired position and again clamping it firmly by means of the cross bolt E. The plate F, secured to the back end of the tool holder, provides means for adjusting the depth of cut and also preventing backing away from the work.

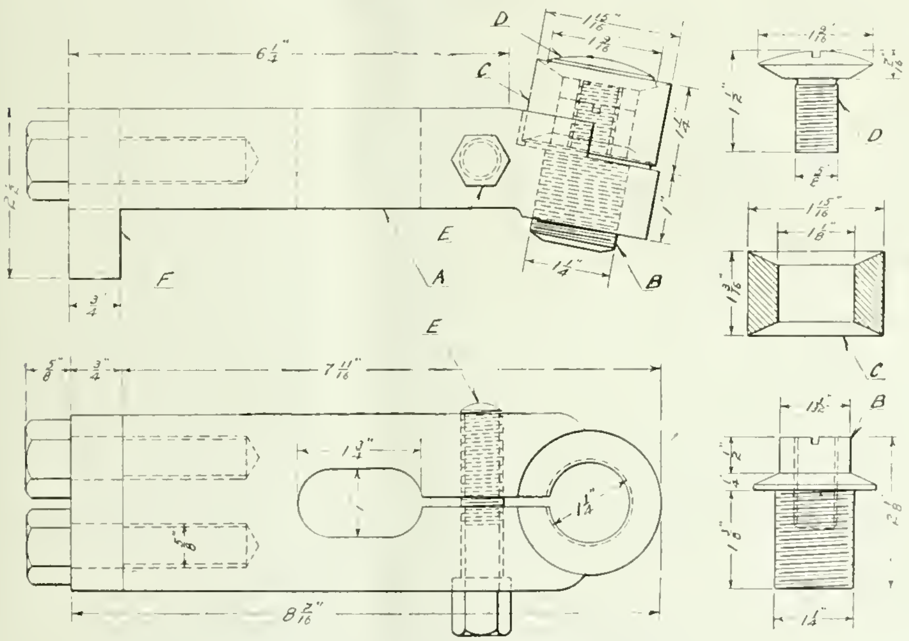


FIG. 1. SPECIAL CIRCULAR TURNING TOOL.

Fig. 2 shows a plan view of the tool in position on the tool rest, with clamping and side adjusting bolts, the latter being necessary to maintain the cutting tool in the same relative position on the shell as the roller occupies on the cam; or in the case of the radius arm, in the same radial line as the centre of the profiling link. From the sketch, Fig. 2, it is clear that the circular tool here illustrated will not have those objectionable features that are so pronounced in the ordinary type of turning tool. When the cam has been developed for a certain diameter of cutting tool, the variation of the cutting point between G and H will remain the same irrespective of how many times the circular tool is set, care being taken to have it always at the same height after regrinding.

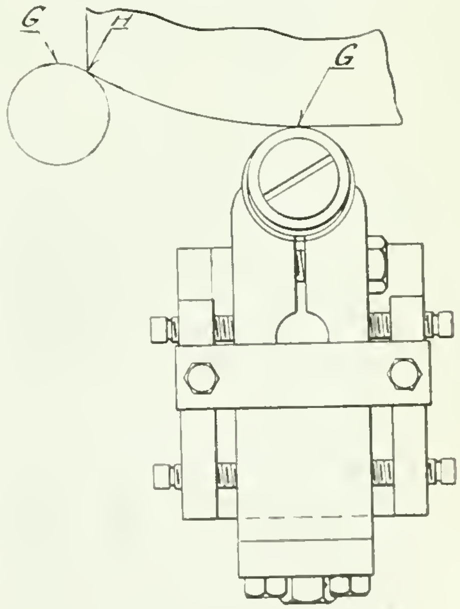

FIG. 2. SPECIAL CIRCULAR TURNING TOOL.

PULLEY TURNING RIG

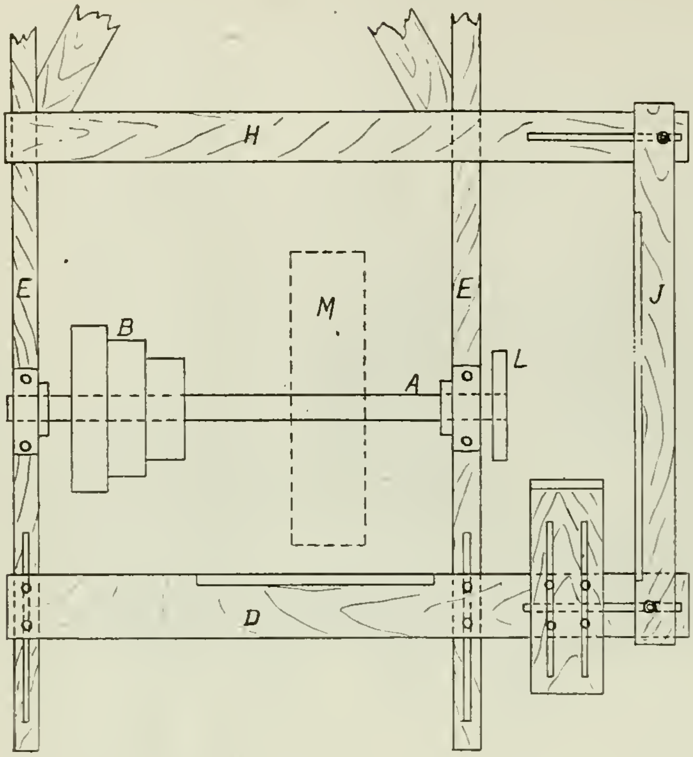
By J. E. McCormack

THE accompanying sketch shows the plan of a rig which I fixed up and used for turning pulleys. The size and proportion of the parts should be governed by the class of work to be done. I use this one for pulleys up to 28 in. dia., with bores of 1½ to 3 in., and used 2x4 in. scantling for the pieces EE, and 1x4 in. for legs and braces, these parts being made of wood. The arbor used was 1 7/16 in. dia. and 3½ feet long, and is driven by the cone pulley B.

The dotted lines at MM indicate the position of a pulley to be turned. L is a disc or face plate. D and H are supported by the side pieces and in turn support the chisel rests C, K, J. These are adjustable and removable in much the same manner as the long and short rests in wood turining lathes. D is movable to and from the arbor to accommodate differently sized pulleys.

The arbor is held from end motion by a collar just inside the frame and against the bearings. Two collars only. One could be put on each side of one bearing if preferred. The bearings are raised so that the center of the arbor is four inches above the upper surface of the pieces EE, thus allowing room for D C J K without raising them too high for convenience. A supply of bushings is kept for use in fitting pulleys of different bores to the 1 7/16 in. arbor.

Very small pulleys are turned on the face plate, being held by a pair of wood screws passing through the disc. The end of the arbor can be fitted with pin or screw as desired, but I did not do so, and, perhaps because of this, I found that in making small pulleys it was better for one not to bore them until after



HOME-MADE PULLEY TURNING RIG.

they were turned. After finishing, I make a few circles on the side by using a pointed chisel on the rest J and these serve as a guide for centering exactly when setting up the work, and any slight shifting of the work previous to the lighter finishing cuts does not throw the finished pulley out of true when hung.

FIXING A BALKY VALVE

By J. E. McCormack

SOME time ago I was asked to fix a balky hand force pump of the type in which valves are made as in Fig. 1, the same piece of leather serving both as gasket and as valve flap. On one side of the flap there was a brass plate covering most of the said flap and held in

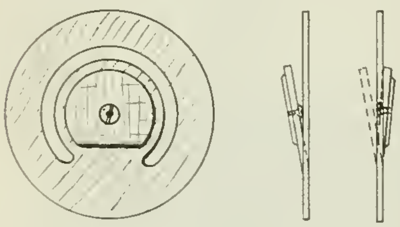


FIG. 1. FIG. 2.
OVERCOMING TROUBLE WITH HAND FORCE PUMP VALVE.

place by a screw passing through the leather and screwing into the plate. The head of this screw was broad, yet thin, and was slotted for a screw-driver. Of the three of these valves in the pump not one of them seated properly, because the leather had acquired a "set" in a shape that kept the flap sticking up, as shown in Fig. 2.

By removing the leathers from the pump, taking the screw out, and putting the plate and screw each on the opposite side of the leather from what they had been before, and then putting the leathers back into the pump other side up from what they formerly were, I secured the aid of this "set" in the leather to help hold the valve to its seat. After treating each valve in this manner, and priming the pump, it held water O.K., and worked satisfactorily right along although the less drastic remedies previously applied had proved unsuccessful.

SPECIAL PATENTED ROLLER CHUCK

By S. B.

AN outstanding feature in connection with the manufacture of munitions has been the great variety of chucking devices that have been designed and constructed for rapid production and economic operation. In general, the practice has been the utilization of the collet chuck, which is operated either by pneumatic power or hand appliances. Several manufacturers have however, adopted the self-acting type, where the gripping device is automatically operated, initially by the action of coil springs, and subsequently by the force of the cutting tool upon the work. The one shown in the accompanying sketches is of the latter type, and carries with it a somewhat interesting history. After constructing this special roller chuck, and demonstrating its remarkable efficiency, the designer, H. E. Bourassa, manager of the Modern Tool Mfg. Co. of Montreal, had the device patented, but not wishing to place any obstacles in the way of maximum production, the drawings were submitted to the Imperial Munitions Board, with the suggestion that any manufacturer desiring to equip their machines with these chucks would be privileged to do so, and could also secure additional drawings and further details for the construction of same. In appreciation of the patriotic spirit of the donor, the members of the board and other interested parties presented Mr. Bourassa with a beautiful diamond ring, a gift that has been more highly cherished than any

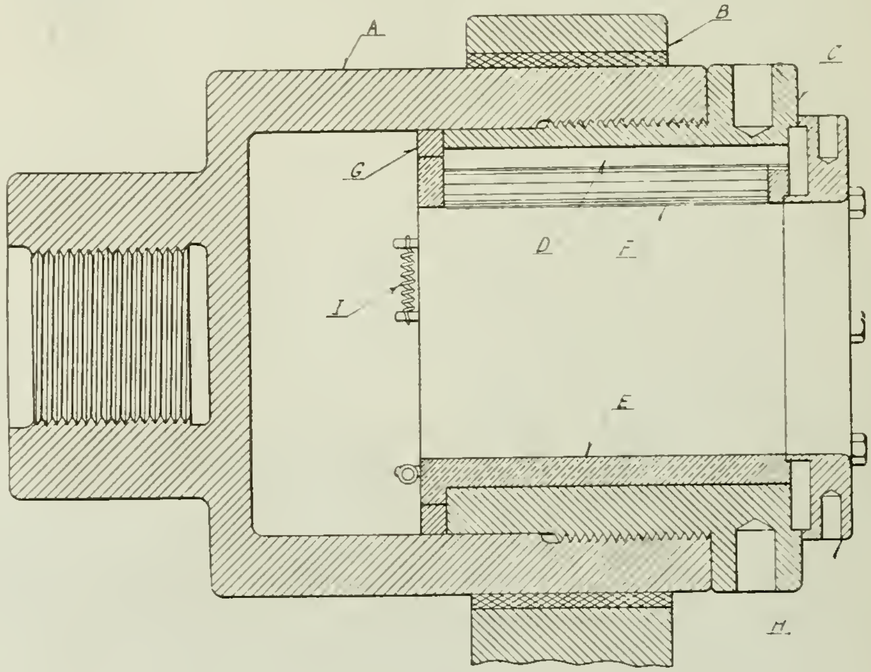

FIG. 1. ROLLER CHUCK FOR 6-INCH SHELL.

monetary consideration would have been.

The chuck here shown was developed from a previously employed collet chuck, the parts A and C being utilized for the new roller type. The piece C, formerly used for the operation of the old style, was slotted out to receive the three hardened tool steel cams D, placed equi-distant around the inner circumference.

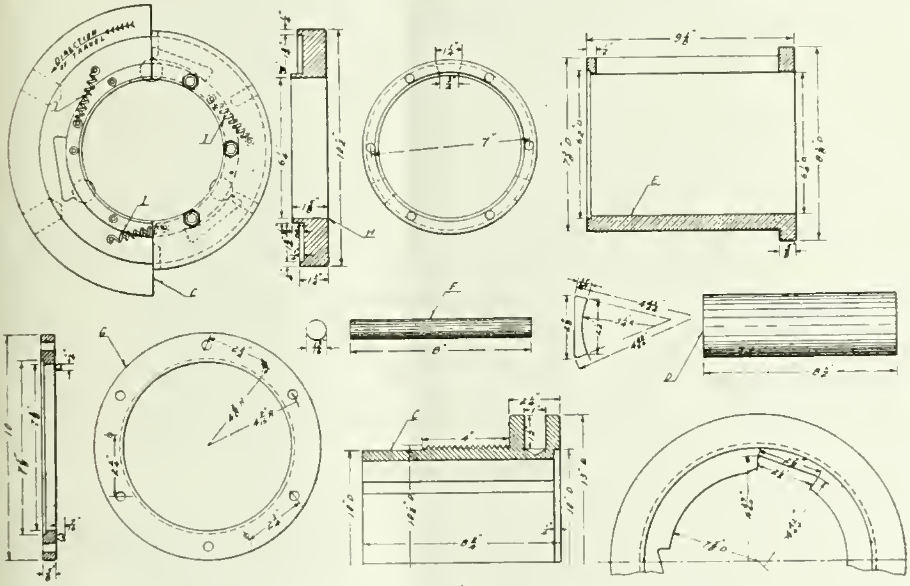

FIG. 2. ROLLER CHUCK FOR 6-INCH SHELL.

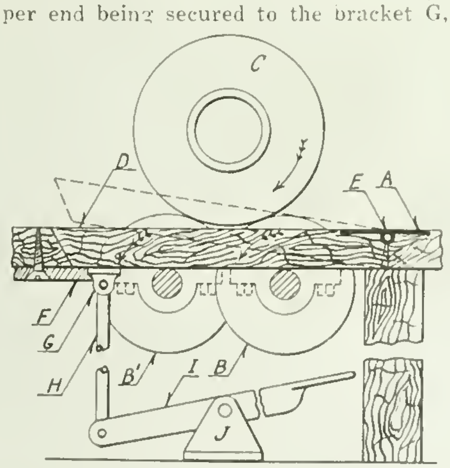
These cams are 8½ inches long and 2⅞ inches wide, the contact surface for the rollers having a width of 2½ inches. Fitted to the bore of the piece C is the brass sleeve E, having three equi-distant dovetailed slots 8 inches long to receive the hardened tool steel rollers F. The shape and position of the containing slots prevent the rollers from being dislodged when the shells are removed from the chuck, and also retain them in their relative positions of 120 degrees apart, thus insuring a uniform and concentric grip with the axis of the shell, irrespective of any slight variation of the outside diameter. Retaining rings G and H, one on either end, keep the mechanism in a permanent position, being prevented from lateral movement by their position in the piece C. The front or outside retaining ring H is made wide enough to provide for operating pin holes as shown, and the inner surface is recessed out to receive the springs I, these springs being used for placing the initial pressure upon the body of the shell.

When the parts are bolted together, the brass bush with the three rollers is free to remove through a small angle, the chord of which will not exceed 2½ inches, this being the length of the operating portion of the cam. The back retaining ring G is secured rigidly to the piece C, and one end of the springs is fastened to this fixed portion (in relation to the chuck body), while the other end is placed on studs in the ends of the brass bushing. This chuck has given the best of satisfaction, is easy to operate, and owing to the almost entire absence of friction in the parts, the wear is reduced to a minimum, consequently repairs are seldom necessary. When repairs are required, the chuck can be easily dismantled and repairs effected.

SHELL HANDLING DEVICE

By R. Hamilton.

WHERE rollers are used for the revolving of shells while applying the varnish to the interior, it is necessary that the shell be raised a short distance in order to place it upon the rolls; and where a large number of shells are handed each day, it entails considerable energy to place them on and off the rolls. To reduce the labor required for this operation and at the same time facilitate the moving of the shells during the process of varnishing, one firm devised the fixture shown in the accompanying sketch. A section of the bench between the two pairs of rolls was first cut out, and the piece D fitted in, this piece being hinged at one end as shown at E, the opposite end being supported by a suitable bevel, and also the plate F, which is securely fastened to the solid portion of the bench. As the shells are rolled along the bench from left to right, the swinging piece D is pushed upwards by means of the foot treadle I and the vertical rod H, the upper end being secured to the bracket G,



SHELL HANDLING DEVICE.

and the foot treadle fulcrumed in the bracket J, this being bolted to the floor in a suitable position. The rollers are revolved by means of a small belt running on a pulley secured to the back end of one of the roller shafts. The motion of the revolving shaft, as shown by the arrow, permits the shell to roll freely away when the centre board is moved upwards, raising the shell from the two rolls.

G.T.R. STRATFORD APPRENTICES' ANNUAL BANQUET

THE twelfth annual banquet of the G. T. R. Stratford shops apprentices took place on Saturday evening, June 16, in the spacious hall attached to the plant. Those occupying the head table were Master Mechanic C. Kelso, A. W. Smithers, of London, Eng., chairman of the Grand Trunk Railway Board; W. D. Robb, of Montreal, superintendent of motive power of the Grand Trunk; H. R. Safford, of Montreal, chief engineer; H. R. Semple, Toronto; D. McCuaig, master mechanic, Toronto; E. R. Battley, Portland, Me., formerly an apprentice in the local shops; G. Meldrum, Montreal, supervisor of apprentices; C. A. Mayberry, principal of the Collegiate Institute; Chas. Farquharson, president of the Board of Trade; Mayor J. D. Monteith, James Powell, H. E. Whittenburger and W. A. Booth, Toronto; R. H. Fish, superintendent, Stratford; and Robert Patterson, of Montmagny, Que., formerly master mechanic of the local shops. The large assembly hall was tastefully decorated with flags and red, white and blue electric light bulbs.

After the toast to the King had been duly honored, the chairman then called upon Ald. Chas. Farquaharson, president of the Board of Trade, to propose the toast to "Our City," to which Mayor Monteith responded.

Grand Trunk Railway System Toast

C. A. Mayberry, in proposing the toast of the "Grand Trunk Railway System," simply requested the guests to arise and drink the toast, to which A. W. Smithers replied. Mr. Smithers deemed it a high honor and privilege to be present.

In referring to the war, Mr. Smithers, who came out from England about five weeks ago, assured those present that England appreciated everything Canada was doing. She realizes that it is harder to get men together over such a wide range of territory, whereas England is so compact.

The Apprenticeship System

The toast to the apprenticeship system was proposed by H. R. Safford, who said that he was convinced, after seeing the work of the boys, that the apprenticeship system in Stratford was a success and that the boys liked it. "I know by looking at the boys that they will make a success of life," said the speaker.

This toast was responded to by W. D. Robb, superintendent of motive power.

A toast was proposed to the visiting apprentices by Mr. Frame, of the local apprentices, and responded to by representatives of Montreal, Battle Creek and Ottawa shops.

After Robert Patterson, the late master mechanic, had expressed his pleasure at being present, the proceedings terminated with the singing of the National Anthem.

Canadian Manufacturers' Association Convention

The importance of this annual function shows an increasing tendency with each succeeding year, due, of course, in large measure, to the recognized necessity of furthering our resources and industrial development from within, so to speak, and to the end that same be done as effectively as possible, so that we both appropriate and maintain a foothold in the world markets, while at the same time strengthening our position in strictly speaking domestic markets. The convention just closed has been marked by a free and whole-hearted investigation of the many problems involved, which will not fail to react beneficially.

PRESIDENTIAL ADDRESS BY COL. THOS. CANTLEY

NOT the least interesting feature of the annual convention of the Canadian Manufacturers' Association held in Winnipeg last week was the address by the retiring president, Col. Thomas Cantley, president of the Nova Scotia Steel & Coal Co.

Referring at the outset to the industrial advancement in Western Canada, Col. Cantley said that from a manufacturing standpoint, the development of the Western Provinces has fully kept pace with their development in other directions. With characteristic enterprise, their citizens have freely utilized the resources at hand to make themselves as independent as possible of outside sources of supply. In milling, in their preparation of animal products and in similar forms of production, there is no reason why the West should not greatly excel. In the heavier lines of manufacture her growth has been retarded by the high price of coal and power, but this difficulty, I am informed, is already partially overcome by the development of hydro-electrical energy, with a good prospect that further, if indeed not complete relief may shortly be had through the utilization of the vast deposits of lignite with which the West abounds.

Problems of the Day

The various problems upon which the Canadian Manufacturers' Association has been engaged during the past year are fully discussed in the reports submitted. As these reports are presented, it will become increasingly apparent that the direction of our activities was frequently beyond our control, in the sense that it was forced by unusual conditions brought about by the war. We have been passing through times of uncertainty and stress, and we must be prepared to face greater uncertainty, and still greater strain before the Empire and our Allies have won liberty's great victory.

Labor has never been in so great demand in Canada as it is at present, and never so highly paid. Manufacturing materials of every kind have greatly advanced in value, and are still daily becoming increasingly difficult to secure. In some instances the prohibition of their export from other countries has made it necessary for us to have recourse to inferior substitutes. For a considerable portion of our normal products there has ceased to be a demand, so that many manufacturers have had to adapt equipment to the manufacture of new products, and cultivate new markets. The movement of traffic has been attended by exasperating delays. Owing to the shortage of production and the difficulties of transportation, coal has advanced to famine prices, threatening to deprive us of both heat and power. Our expenses have been increased by the necessity of providing liberal compensation for industrial accidents. Our Legislatures, meanwhile, have added to the list of statutes that tend to interfere with—when they should facilitate — inter-provincial trade, and over and above all these troubles we have begun to feel the burden of taxation which before long must fall with even greater heaviness upon us as the war indebtedness of Canada becomes greater.

Association Aims

Be it remembered that the real function of the Association is to give service, to advance and protect the interests of Canadian manufacturers, to foster the growth of Canadian manufacturing industries, and to assist in the development of Canadian export trade. So long as we keep within these general limitations, we are engaging in legitimate work, and within our sphere of influence —when we exceed these bounds, we are liable to both encounter and make trouble.

So far as criticism of the Federal Administration is concerned, wisdom suggests that every such organization as ours should move slowly and circumspectly in times like the present. We never have had and never in our time will have a perfect Government. Perchance the present day may be no better than its predecessors—but it has larger problems, greater responsibilities and more difficult duties confronting it than any previous Canadian Government has been called on to face. Destructive criticism is useless. Can we show a better way? If so, express it. Do the Government courageously meet an awkward difficulty? Applaud. Are they vigilant and energetic and fair? Give them credit at least.

COL. THOMAS CANTLEY.

Manufacturers Unfairly Criticised

Perhaps this point has been unduly dwelt upon because of my unwillingness to believe that some of the criticism that has been leveled against the Government may have been quite as unfair and quite as unjustified as much of the criticism that has been leveled against the manufacturers. Man for man, the manufacturers are probably as good citizens as any other class in the community. They courageously kept the wheels of industry in motion at a time when the country was becoming panic-stricken over the prospects of unemployment. They have conscientiously applied themselves to the task of providing the materials needed for the carrying on of the war. They have worked indefatigably to surmount difficulties by which many an armchair critic would have been overwhelmed. They have responded generously to every call for subscriptions to the Patriotic, Red Cross, Naval and other war funds, and have done their duty by various Canadian war loans, yet it has become the fashion from one end of Canada to the other to revile them as profiteers, trafficking in the blood of their country, mainly because a comparatively small number of them have shown large profits.

It is not accounted unpatriotic of the farmer if he is now receiving good prices for all his products. The artisan is not held up to condemnation because he now receives four to six dollars per day in payment for work he gladly did for two and a half or three dollars before the war. The pay of the British soldier is one shilling per day, and maintenance, but the Canadian soldier is not thought to be bleeding his country because he draws $1.10 per day for similar services. Yet the manufacturer is scourged with abuse if he makes a profit on business which he accepts at a price in many cases below that paid for similar work and service to American and British manufacturers.

Taxation of Profits

The cumulative effect of this tirade of abuse is now being felt by our successful manufacturers in various ways. Notwithstanding the fact that wages are on an unprecedently high scale, it is being alleged that they are grinding the faces of the poor, and the demand is being made that they should pay still higher wages. Our Legislatures are scaling up the compensation allowances, and in case of permanent partial disability are saddling industry with annuities that may easily represent more than 100 per cent. of wages when the latter are reduced to a reasonable basis, as in time they must be.

In some quarters it is being suggested that the supposed enormous profits made from manufacturing would justify the Government in removing the protection of the tariff. In other quarters it is being seriously advocated that the entire expense incurred through Canada's participation in the war be met by the taxation of business profits. Last year the Federal Government saw fit to provide itself with an emergency revenue by levying a tax on business profits, and although the amount secured largely exceeded their expectations, they have recently announced that that tax is now to be very substantially increased, presumably to some extent in deference to this uninformed public opinion.

It is greatly to the credit of manufacturers as a class that in the face of so much provocation they have avoided any display of resentment. They have paid and will continue to pay their war taxation with cheerfulness, trusting to a reasonable administration to secure them fair treatment. They have done their duty by the dependants of employees who have gone to the front, and will likewise do their duty by the soldiers who return. They will come to the assistance of the farmer this year, by releasing men to help him with the harvest, and they will pay high wages just as long as the condition of their business makes it possible to do so.

After the War

A time will come, gentlemen—and it may come sooner than some of us think—when the manufacturer will be unable to carry the load he is carrying to-day. Had he been asked five years ago whether he could continue to do business at a cost for labor and material such as he is paying to-day, he would have laughed the question to scorn. Yet he is in business and making a profit, but only because there are governments that still must have supplies and are prepared to pay the price. That demand will collapse with the termination of the war, and prices will immediately fall. Twenty millions, perhaps more, of the forty million men who have been withdrawn from producing and other occupations, will return to their homes and to such employment as may be offering. National borrowings of staggering proportions will have to be repaid, and the only way they can be repaid will be by the countries' increased production. A world that for three years has to some extent neglected commercial production will suddenly apply itself thereto with greater zeal than ever, with the result that we will witness an era of competition such as has never been known before. Under these circumstances all prices must tend steadily downward, and wages must do the same. The profits accruing from manufacturing will narrow in proportion until we reach a point where capital will temporarily cease to be attracted to industrial enterprise.

To all of us who have given the situation any serious thought, two facts must stand forth conspicuously. From the standpoint of production there will be gradually but surely cut off from us an export trade in war materials amounting now to perhaps $800,000,000 a year. Manufacturers cannot immediately adapt themselves to new lines of production, nor can they immediately find new markets. With the coming of peace, there will necessarily be a period of pause, of readjustment, with delay of development until the general business situation becomes clarified sufficiently to justify the employment of capital in new ways. There will be a widespread release of men now engaged in the manufacture of munitions and military supplies, probably numbering 100,000 to 150,000. These large numbers will be steadily added to by the soldiers returning from the front, for most of whom employment will have to be found.

A Sound Fiscal Policy Desirable

It may well be borne in mind that no solution will give satisfactory and permanent results that is not based on the principle of supplying as far as possible our own wants and producing in addition thereto something exchangeable at a profit for such commodities as we do not grow or cannot produce. Such a policy will lift us out of debt and set our feet on the highway of prosperity.

In the troublous times still ahead of us this country will need all the help she can secure from men of enterprise, from men of business capacity, who, when opportunities present themselves, can quickly secure and employ the requisite capital to bring profitable industry into operation. Canada can best obtain that form of help by shaping her fiscal policy so as to create opportunities for home and foreign business, for, given opportunities, capital and enterprise will do the rest.

The wisdom of a sound fiscal policy could find no better proof than in the magnificent service rendered by our manufacturers since the outbreak of the war. During thirty-five years of moderate protection, Canada was able to build up for herself a large and varied industrial equipment of first-class efficiency. The speedy adaptation of that equipment, supplemented by very large investment in new plant, probably exceeding $25,000,000, for the production of munitions and war supplies, not only enabled Canada to render assistance of immeasureable value to the Allied cause, but it also enabled her to keep her workmen fully employed at high wages at a time when, but for her possession of that equipment, and but for the enterprise of her manufacturers, Canadian artisans would have had to seek employment beyond her borders.

Our national policy of tariff protection never needed any justification for the results always spoke for themselves, and if it did, then surely the wonderful achievements of the past two and a half years have furnished that justification in abundant measure, and discredited the free trade propagandists who have consistently sought to belittle the importance of our manufacturing industries. These industries have done yeoman service in the cause of freedom, not the least important features of which have been the contributions they have enabled Canada to make to the army in fighting men, and to the treasury in money.

Again, these industries of ours will continue to give a good account of themselves under a policy of moderate protection, for, notwithstanding new conditions, opportunities will arise of which discerning manufacturers will be quick to take advantage.

Shipbuilding

The address next referred to the possibilities of developing a great steel shipbuilding industry, reviewed the history of the business in Canada, the natural opportunities afforded, on the Great Lakes, the St. Lawrence, and the seaboard, spoke of the experience of the United States, showed how large the amount of capital required would be, and what industrial advantages would follow, and concluded:

"A bounty that would provide sufficient encouragement would quickly stimulate the growth of shipbuilding, supply the incentive for the establishment of plate mills, and would lead to the specialization of our engineering trades. This would be followed by a two-fold advantage—first, in that it would shorten the time and cheapen the cost of constructing vessels and so make it possible for the industry ultimately to get along without a bounty, and second, in that it would open up a wide field for the profitable employment of our returning soldiers, and particularly of thousands of munitions workers, whose present outlook is clouded with uncertainty. Above and beyond all these reasons, however, the building up of a Canadian mercantile marine will insure that the agricultural products of this wide Dominion, as well as its export of manufactured goods, will be carried not only over Canadian railways, and internal waterways, but their transport beyond the seas will be in Canadian bottoms, and the profits resulting therefrom would accrue to the advantage of the Dominion and add to our wealth instead of enriching foreign shipowners, as at present.

Technical Education

On the subject of technical education, the address said: "Canadian workmen as a class are possessed of great adaptability and a high order of natural intelligence, and quickly become expert machine operators, but the Canadian artisan outside of the engineering class usually labors under the disadvantage of not having served an apprenticeship, and of having no opportunity to become familiar with the mathematics and the scientific principles upon which his work is based. In a young country like Canada, whose industries are in the making, there is a constant demand for men who know how things should be done, who understand why they should be done in a particular way, in the only way, and who can instruct others, and who, when things go wrong, can put them right—in brief, trained men who can be entrusted with responsibility. Neither our present factory system nor our educational system makes provisions for the training of such men. In consequence of which our industries and our workmen both fail to make the progress they should, or reap the rewards which their industry entitle them to."

In conclusion, Col. Cantley said: "To those members of the Association present or absent, whose sons have passed over to that great company of immortals, who think of lonely graves somewhere in France, I respectfully tender my admiration of the nobility of your silent suffering, and my sympathy in your sacrifice.

"Remembering what our brothers and sons have done and are doing, the valor and the sacrifice of Britain, the gallantry and endurance of France, the agony and crucifixion of Belgium, and the dreadful sufferings and losses of Serbia and the other Allies — recalling these things, it is our duty as Canadian manufacturers, as citizens living in this country—in prosperity, in comfort, no enemy yet on our coast daring to make us afraid —recalling these it seems to me that we should work as never before—for production is essential. We must pay as never before. We should do it honestly, we should do it cheerfully. We should support and encourage the Government of the country, whatever be its political complexion, so long and so far as the members of the Government are actively and energetically engaged in prosecuting the war. Let us remember that they are human, not infallible, and generally quite as patriotic as ourselves. If we are to help as we should, and can, we must be open-handed, in some sense sentimental, and abundantly sympathetic.

"We meet under the shadow of a great war—a war beyond all historic precedent—a war for the preservation of human liberty, in which not only the Motherland, the sister Dominions, and our own country, but other Allied nations, are vitally engaged. In the titanic and deadly struggle in which your sons and mine, and those of many of our fellow-citizens throughout the Dominion, have been for many weary months engaged, thousands have daily gone down to the Gates of Death, and many have already passed its portals, having won glorious immortality, sacrificing their young lives for their country and world liberty..

"It seems to me that it befits us now for a moment to turn our thoughts to them, to recall their courage, their endurance, their valor, their gallantry — those who have given all, those yet alive, but who are daily risking their all—let us thank them, let us honor them—these gallant knights who have done so much to advance the glory, the honor of Canada, and the stability of constitutional government and freedom not only in this Dominion, not only in the Empire, but in Europe and the world."

SYNOPSIS OF PROCEEDINGS

THE forty-sixth annual general meeting of the Canadian Manufacturers' Association opened in Winnipeg on Tuesday, June 12. The various sessions were held in the Convention Hall of the Fort Garry Hotel and were attended by a large number of manufacturers from all parts of the country. On Tuesday evening a reception and smoker was tendered the visiting delegates by the Winnipeg members of the Association, brief addresses of welcome being delivered by Mayor R. D. Waugh, of Winnipeg, Hon. T. C. Norris, Premier of Manitoba, and W. R. Ingram, Chairman of the Prairie Provinces Branch of the Association. Fitting replies were made by Col. Thomas Cantley, president of the Association, S. R. Parsons, of Toronto, first vice-president, and W. J. Buman, second vice-president.

At the first business session on Tuesday morning, reports of the secretary and treasurer were read, and the presidential address delivered by Col. Cantley. The afternoon session was occupied by the reports of the executive and insurance committees. On Wednesday morning the legislation and tariff committees submitted their reports, and in the afternoon the transportation committee report was read. On Thursday morning amendments to by-laws were taken up, followed by the election of officers and committees. The feature of the meeting was the presidential address by Col. Thomas Cantley, a synopsis of which will be found in another section of this issue. Summaries of reports of the various committees are as follows:

S. R. Parsons presented the report of the Executive Committee in which it was pointed out that the Association's revenue for 1917, $66,623.30, was the largest it ever enjoyed. By the Trade Index a profit of $2,242.40 was yielded, and the earnings from Industrial Canada showed an increase of $613.33, the sum of $376.54 being received in the way of interest on investments. However, there was a deficit on the year's operations of $5,535.15, whereas there was a surplus last year of $4,922.59. To offset present conditions the committee is calling for a general increase in the schedule of membership fees.

High Insurance Rate

The efforts of the Insurance Committee, according to the report presented by W. H. Shapley, chairman, have been mainly directed during the year towards protecting the manufacture in his right of free access to the market for unlicensed insurance.

Following a comprehensive resume of the insurance activities of the year, the committee reported, in reference to the tax on unlicensed insurance, as follows: "The situation meanwhile is that such a tax is operative in Western Canada, but not in Eastern Canada. Our efforts this year have been exercised in trying to protect our eastern members against something which our western members are already suffering from. To be consistent, we ought to work with equal zeal for the elimination of the tax in the West, for there can be no question but what it is responsible for unnecessarily high rates of insurance in this territory, to say nothing of the fact that the existence of such a law in any Province is always more or less of an invitation to other Provinces to follow suit."

In the report of the Legislation Committee as presented by Geo. C. Coppley, chairman, mention was made of the fact that the past year has offered abundant opportunities for work. An outline was given in detail of the legislation passed affecting the association. Included in the list are the Extra-Provincial Corporation Licensing Acts, the Alberta Corporations Taxations Act, the Commission of Inland Trade and the Business Profits War Tax Act. The taxation of the profits of munition manufacturers was dealt with fully, and due attention is paid, too, to Workmen's Compensation, the Alberta Factories Act, the Minimum Wage Bill and the Bulk Sales Act.

Railway Equipment

The necessity for additional railway equipment was brought strongly before the association in the report of the Transportation Committee. Attention was called to the recommendation of A. H. Smith, president of the New York Central Railroad, in the minority report of the Railway Commission, that the Government should undertake at once to provide for an ample supply of freight cars and locomotives against immediate and imperative needs. The committee urged that the convention should make some representations to that effect to the Government.

The valuable work done by the committee in connection with freight rates and other railway matters of prime importance to manufacturers was set out at length in the report. Commenting on the findings of the Royal Commission appointed to inquire in railways and transportation in Canada, the committee emphasized the necessary duplication of railway lines and facilities throughout the country and contended that legislation was absolutely necessary to guard against such evils in the future and to protect investment already made.

The Association closed its convention on Thursday with a discussion of between four and five hours' duration on the Canadian railway situation, and eventually passed a resolution calling upon the Government to take immediate steps toward overcoming the desperate need for equipment by providing an ample supply of cars and locomotives and turning them over to the companies under lease or contract of purchase. The motion also embodied a resolution that a board of trustees be appointed to receive all monies of these companies unable to meet their obligations, and to determine and supervise expenditures of railway companies to whom advances have to be made.

The discussion revealed a desire on the part of a number of the members for nationalization of the railways, and an amendment was introduced asking that the Government put administration of all the railways of Canada under one body with a view to co-ordinating the entire service. This amendment had a great body of support at one time, but on the representation that what was immediately wanted was an increase in railway equipment, and that the greater scheme could be deferred, the motion of the resolution of the committee was carried.

A number of other motions were carried at the forenoon session, among them being one giving hearty endorsation of the Government's proposals for conscription. The patronage system was denounced as being a controlling factor in both Federal and Provincial Governments in determining who should enjoy Government business, and a strong resolution calling for the abolition of this principle was passed unanimously.

Another resolution was passed calling for the establishment by the Government of laboratories for the solution of industrial problems, and another authorizing a delegation to approach the Provincial Government with the view of taking steps to prevent fires, which, it is estimated, caused losses annually of approximately $20,000,000.

New Officers

S. R. Parsons, of Toronto, was elected president for the ensuing year; W. J. Bulman, Winnipeg, and T. R. Howard, Montreal, vice-presidents, and J. F. Ellis, Toronto, treasurer, in succession to Mr. Booth, who retired after over 20 years' service in that capacity, and who, it was agreed, will be given some tangible indication from the association of its appreciation of his long and gratituous service.

The election of members to the Executive Council and various committees was as follows:—

Executive Council, Appointive

Executive Council, appointive:—W. K. McNaught, Toronto; C. B. Gordon, Montreal; P. W. Ellis, Toronto; C. A. Birge, Hamilton; W. K. George, Toronto; C. C. Ballantyne, Montreal; H. Cockshutt, Brantford; R. Hobson, Hamilton; R. S. Gourlay, Toronto.

Executive Council, Elective

Maritime Provinces—Geo. Henderson, Montreal; C. A. Lusby, Amherst; Bruce Stewart, Charlottetown; S. E. Elkin, St. John, N.B.; Angus McLean, Bathurst village.

Montreal—G. F. Benson, Montreal; J. R. Colby, Montreal; W. A. Desbarats, Montreal; S. W. Ewing, St. John's; D. J Fraser, St. John's; Chas. E. Frosset; Carl Riordan, S. J. B. Rollard, G. W. Sadler, Geo. A. Salter, F. W. Stewart, Ferd. Van Bruysell, Montreal.

Quebec City—Jos. Picard, J. H. Gignac, Quebec, Que.

Quebec Province—C. R. Whitehead, Three Rivers; F. J. Campbell, Windsor Mills; J. E. Alain, Victoriaville.

Sherbrooke—E. W. Gilman, Montreal.

Toronto—Geo, Brigden, G. Frank Beer, W. C. Coulter, R. D. Fairbairn, Thos. Findley, E. J. Freyseng, S. Harris, R. L. McIntyre, J. S. McKinnon, T. F. Moneypenny, J. P. Murray, W. C. Phillips, Thos. Roden, W. B. Tindall, J. Westren, Toronto.

Hamilton—H. H. Champ, H. J. Waddie, H. H. Biggert, A. F. Hatch, Geo. C. Coppley, Hamilton.

Ontario — Henry Bertram, Dundas; Don. M. Campbell, Preston; Geo. H. Douglas, Hamilton; Geo. E. Forbes, Hespeler; W. G. Gartshore, London; R. O. McCulloch, Galt; R. S. McLaughlin, Oshawa; W. R. Breyfogle, Peterboro; T. F. Matthews, Peterboro; John Ransford, Clinton; Alex. Saunders, Goderich; T. J. Storey, Brockville; J. M. Taylor, Guelph; H. I. Thomas, Ottawa; H. W. Fleury, Aurora; C. H. Waterous, Brantford; C. C. L. Wilson, Ingersoll.

Prairie Provinces—W. S. Fallis, W. A. Matheson, T. R. Deacon, W. R. Ingram, M. F. Christie, F. W. Drewry, Jas. Carruthers, H. R. Eade, Winnipeg.

British Columbia — Alex. MacLaren, Barnet; A. C. Flumerfelt, Vancouver.

Members of Other Committees

Exhibition Representatives

Representatives to Canadian National Exhibition—R. S. McLaughlin, Oshawa; H. J. Waddie, Hamilton; J. R. Shaw, Woodstock.

To Central Canada Exhibition Association—Geo. H. Miller, Ottawa; Col. J. W. Wood, Ottawa.

To Western Fair Association—Arthur W. White, London; W. N. Manning, London.

To Edmonton Exhibition Association—Geo. C. Robson, Edmonton.

Auditors—Wilton C. Eddis & Sons, Toronto.

Customer—"Send up twenty-five cents' worth of boiled ham."

Butcher—"All right, sir. Anything else?"

Customer—"Yes. If my wife isn't at home, tell the boy to put it through the keyhole!"—Life.

"Now, boys," said the teacher, "there were two rich men; one of them had made his fortune by honesty and industry, while the other had made his by fraud and roguery. Which of these two men would you prefer to be?"

There was a moment's hesitation, then young Solomon Isaac's hand went up as he quietly enquired, "Vich made the most?"

CONTEMPORARY WAR ARTICLES

Embracing Information and Data Drawn from a Variety of Sources Relative to and Arising from the Prosecution of this Many-Sided European War

METRIC SYSTEM, ITS MEANING FOR THE MACHINE SHOP

WHEN the metric system was introduced, manufacture was in its infancy, and the methods of the present had not even come to birth. Only a few people followed "handicrafts." Unification would have been an easy matter then. Later, when Whitworth attempted it in screw threads alone he was confronted with a herculean labor. To-day, the attempt to impose a new system of measurement for the vast total of engineering products in the tens of thousands of shops in England and America would result in financial disaster, and handicap their efforts for a generation to come. Theorists dream of an easy transition, a smooth changing-over from one system to the other, a substitution of dimensions in a price list or catalogue, an obliteration and a beginning anew. The best answer to such a view is to show broadly how much is involved in the present methods of manufacture.

Effect on Drawings

To those who imagine that a change over to the metric system would involve no more than is entailed in the preparation of drawings and designs to the new dimensions, and manufacturing from those drawings, the following facts may be suggested. It may be granted that in so far as the drawings themselves alone are concerned the expense might be negligible, if only all firms were beginning business with a clean slate, but they inherit a legacy and an incubus from the past. During many years of work many thousands of costly drawings representing standard products have accumulated. Made from these are thousands of tools, appliances, patterns, forging-dies, and some specialized machines, all based on the British units of measurement. The drawings are now made with immensely more elaboration than of old, and their numbers are multiplied exceedingly. Formerly only the principal dimensions were inserted, small radii and unimportant sizes being neglected. Again, large-scaled and full-sized drawings were avoided as much as possible, and before the days of cheap prints one dirty and tattered drawing would frequently go the round of several machines. Now the detail dimensions are greatly multiplied. Nothing is too minute to be figured up. drawings of detailed parts are made and printed lavishly, those to full size. or to half or quarter scales, being preferred when size limits permit, but the labor of re-dimensioning is correspondingly increased. To reconstruct, re-dimension, and replace the major portion of these would entail an increase in staff and an expense that only the wealthiest firms could contemplate. It would hinder the undertaking of new orders, and cause confusion worse confounded than any handicap which might possibly arise from the retention of the present system. Yet this would be but the beginning of the trouble. In the machine shop it would become a real catastrophe.

Gear Cutters

The single-edged cutting tools used in lathes, planing and shaping machines and slotters would offer no difficulty, since their dimensions and outlines are not related to any basis of measurement, but nearly all tools outside these groups are so related, and would be affected by the change. As regards form gear cutters, a set of eight is provided for each separate involute diametrical pitch, the eight ranging from 12 to 14 teeth to a rack. and these must be multiplied by the smallest number of pitches which may be stocked, say, perhaps, 20, ranging from 1 to 20 d.p. When for the sake of quiet running very strict approximation to accuracy is required, these sets must be supplemented by other cutters made exactly to the tooth shapes required. Also, where rapid production is studied, the work of the standard cutters which finish is preceded by those of another series which stock-out or gash the tooth spaces with stepped teeth that breaking up the chips, cut faster than the others.

When there is a demand for gears of circular pitch, an entirely distinct set of cutters is necessary, 24 in number, since the sectional shapes are those of double curves. For bevel gears other sets of cutters are required, thinner than those used for the spurs, to permit the cutters to pass between the small ends of the teeth. Again, as the gear cutting machines are built in different dimensions and capacities, the arbors of the heavier machines are of larger diameters than those of the smaller ones. Consequently the holes in a set of cutters made for one machine will not fit the arbors of machines of other capacities. Further, while large stocks of cutters of carbon steel have been accumulated, there are in addition ever growing stocks of those of high speed steel.

In the generating methods employed for spur gears and worm wheels, and for some worms, large numbers of hobs are used. For spurs there must be as many hobs as there are pitches, and these tools are very costly. The worm wheels vary not only in reference to pitch. but very much more so in the worm diameters, in lead, and in numbers of threads, from single to quadruple; and for every variation in each kind a distinct hob is required. so that the stock of a firm doing a large business may number some hundreds of expensive hobs. Hobs are also made tapered to be fed longitudinally. Another group of cutters is required for double helical gears of spur and bevel types, operating endwise or normally to the surface on which the teeth are produced.

The milling cutters and many of the gang mills are only a variety of the gear-cutting class—that is, they operate in precisely the same fashion, and they are form tools, although their functions are not the same. The stocks of these cutters are not inferior in numbers to the gear cutters. In many shops they would comprise a larger group, but only a moderate proportion are dimensioning tools, and these chiefly occur in the gang mills. The grooves and dove-tailed grooves in machine tools are milled with solid cutters, the dimensions of which are fixed. The cutters for sprocket wheels also are of fixed dimensions, and so are key-way cutters and those for slitting screw-heads. Where cutters are put on arbors, the bores would be affected by a change in dimensions, and those with solid shanks have standard tapers and diameters.

Drills and Reamers

In their close approximation to accuracy of dimensions, drills, reamers, and boring tools rank as high as any other tools. As in the gear cutters, the question of changing them over to metric measures can only be answered in the negative. They must be exactly to size.

Consider for a moment how enormous is the stock of drills and allied tools which a machine shop has to carry, ranging, say, from ¼ in. up to 6 in., advancing by sixteenths, and frequently by thirty-seconds in the smaller sizes. Many are required in more than one type. Of twist drills, which predominate, some must have straight parallel shanks, others shanks' tapered to Morse or other standards. Some have flutes of constant angle, others with increasing twist. Many are of high-speed steel. Another large group of drills lies outside these forms. Instead of the regulation two flutes, some have three of four grooves. For brass work, straight-way drills are used rather than the twist form. There are many twist drills in use made as were the original ones by twisting a flat bar of steel. A large number of the old flat-lipped drills are still employed, in preference to the twist forms. D-bits are a large group. Tap drills are a large class, each being made for one size of hole to be tapped, and these are multiplied in sets for Whitworth, gas, and other standard threads. Finally, the lengths of drills of the same diameters vary from normal lengths, being shorter or longer for special duties.

For a large proportion of the drills, the requirements of high-class and interchangeable work can be met only when there is a corresponding reamer to finish the hole to precise size. These tools also have parallel and tapered shanks. Many have parallel flutes, others spiral ones, with plain and rose ends. Again there is a large group of chucking reamers used in chucking machines, turret lathes, and automatics, having straight and spiral flutes. There are also floating and expanding reamers, both tapered and of shank and shell types.

Screwing Tackle

Taps, dies, and allied tools, whether used by hand or operated in machines, present another tremendous problem which manufacturers would have to solve in the event of a change in measurement. If it only involved the sets of hand-taps and dies, as in the old days, the task would be a colossal one. Yet that is a very small affair by comparison with the field now occupied by machine-cut screw threads, which embraces the solid dies and taps which are used in turret lathes and screw machines, and in the screwing machines for bolts, nuts, pipes, etc.; tools that are gripped in holders, the rotation of which is reversed after the thread has been cut; together with the opening dies and the collapsing taps which are used in ever-growing numbers in the same classes of machines, in which the holders do not reverse, but where the chasers are caused to fly open in the dies and collapse in the taps, when the end of the thread is reached. There are several designs of these, and a large range in sizes, and in systems of threads. The thread-milling cutters are another growing group.

Measuring Instruments

Appliances such as instruments of measurement and jigs and fixtures present as formidable a barrier as the tools do to the change contemplated. Instruments of measurement include all the forms of divided callipers, fitted with the vernier or with the micrometer screw, each one suited only for the system for which it is graduated. The principle of division and the graduations are applied also to measuring tools other than the callipers, as in depth and rod gauges and in the costly standard measuring machines for shop testing of tools.

There are also the fixed gauges, which total to an appalling aggregate in present-day practice. Their numbers are always increasing, and none of them would be of any value as they stand, without correction or renewal, for any system of measurement but the one they are made for. The reference or standard tool room gauges come under the same category, as, too, do all indicating tools that have graduations, and all the rules and the scales used in offices and shops.

In any machine shop of average size where interchangeable manufacture is carried through, the jigs and fixtures aggregate many thousands. A change over in measurement would condemn a large proportion of them to scrap, and if the main portion might be saved, many fittings would have to go. All bushings for drills and reamers would be incorrect, as would also be many of the minute adjustments by which tooled parts are set, and the readjustments which would have to be effected would often entail nearly as great expenses as the making of a new jig or a new fixture.

Machine Tools

To assume that the machine tools — the plant of a shop—would not be touched by a change in measurement would indicate superficial knowledge. Main framings, shafts, spindles, broad outlines, and arrangements, and many details would not be affected. But much more than these goes to the making of many machine tools. The lead screws of lathes would have to be changed, as would their clasp nuts, and the chasers or master screws of turret chasing lathes, and of the vast numbers of Fox lathes used by brass finishers, with their die nuts. There are also the feed screws and their nuts, and micrometer dials which now indicate advances in thousandths of an inch. Many machine tools have steel rules on faces and edges to facilitate settings of work. Costly boxes of gears provide ranges of feeds. Collet jaws grip definite sizes of rolled bars. Spindles of lathes, of boring, drilling, and milling machines, are bored and ground to receive the Morse or other standard tapers, based on the inch. Enormous numbers of turret lathe tools, many being very expensive, used on turret, cross-slide, and chasing saddle, are standardized on the basis of the inch. These would have to be re-made or discarded before a change could be completed. Grinding wheels would be a source of trouble, since their holes would not fit metric spindles and arbors. The large stock of arbors or mandrels used for grinding wheels, milling and gear-cutting machines would be incorrect, and all the solid mandrels that are stocked for chucking through bores.

Gears

Another complicated problem is presented by gears, since they are used on machine tools and on an infinity of motors and machines, in which the past, as well as the present, is involved. The old cutters must needs be retained, else worn and broken wheels could not be replaced. The cutting of gears in the present and future to module proportions would cause trouble because diameters and shaft centres would be affected—unless, indeed, approximations should be tolerated, in which case the ideal would be sacrificed. All wheels would come under the influence of these drastic changes—spur, helical, spiral, bevel, worm, and the circular and involute pitch systems.

Re-dimensioning

It has been suggested with more ingenuity than knowledge that the contemplated change might be made by retaining the present tools, gauges, drawings, etc., and re-dimensioning them in terms of the millimetre. Surely those who think thus cannot be qualified to offer an opinion on the subject that would commend itself to shop managers. Tens of thousands of tools and appliances would have to be re-measured and re-stamped in a machine shop of only average size; many hundreds of thousands of new dimensions would have to be inserted on drawings. Often it would be cheaper to scrap tools and drawings than to take such a task in hand.

Supposing, however, this herculean labor to have been accomplished, the new system would still be but a bastard one, because the inch and metric measures are not interchangeable. A metre measures 39.37 in., and the inch equals 25.4 mm., and they are not translatable, apart from the use of tantalizing decimals. If this irreconcilable bastard system should be followed, or a true metric measurement adopted, two standards would have to be maintained for a generation or more. This would entail, in addition to the appalling expense of renewals, the doubling of storage spaces and of bookkeeping, an increase in the staff and in the number of hands, and an enlargement of machine tool areas.—*Times Engineering Supplement.*

DOMINION STEEL CORPORATION ANNUAL MEETING

"WE are booked up in steel products to the end of the calendar year," President Workman told the shareholders of the Dominion Steel Corporation at the annual meeting last week, "and in addition to that our shell steel output for the first six months of 1918 has been disposed of." This was supplemented later on by the president's statement that unfilled orders at the present time were double those of a year ago and further that the business was not subject to cancellation.

Mr. Workman reviewed in some detail the improvement in the financial position of the corporation effected in the past year by the retirement of notes, etc., and the elimination from the balance sheet of the item of $2,000,000 "discounts and premiums on securities" which involved a recurring annual charge of about $225,000. For the current fiscal year he estimated that the annual interest charges would be about $500,000 less than two years ago—this in addition to interest on bank loans which have been eliminated.

Plant Improvement

As to physical improvements at the plants the remodeling of the blast furnace department was making progress and two batteries of new by-product coke ovens were being installed which would result in lower coke costs, while permitting of the utilization of the company's total blast furnace capacity which is now greater than can be taken care of owing to the limited coke production. Difficulties in the coal department due to scarcity of labor and ships were dealt with in some detail, but the president indicated that the outlook for the current year was fairly satisfactory. In a general review of the present position and the after-the-war outlook, Mr. Workman had this to say:—

"While the statements now before us indicate a greatly improved condition as compared with the previous history of the corporation, it must not be forgotten that lean years have been the rule rather than the exception, and it must therefore, be my policy to exercise conservation in all our undertakings. I feel particularly committed to this course, having in view the keen competition that will undoubtedly arise after the war.

"Many corporations engaged in the steel industry across the border, have been able, partly through exemption until a comparatively recent date from taxation, and partly by reason of other advantages resulting from the attitude of neutrality long maintained by their Government, to accumulate large surpluses, and to practically amortize their plants. We, in Canada, have borne responsibilities of this nature for a much greater period, and it must not be lost sight of, that however gladly and willingly we have shouldered the burdens which have fallen upon us as our share in the prosecution of the war, none the less does this condition demand careful study and the exercise of rigid economy, in order that we may not be placed in a position of disadvantage os regards our competitors.

When Peace Comes

"Our chief problem, therefore, lies in the meeting of the conditions which may arise after peace terms have been signed, and I consider it good business to fortify ourselves in every possible way, so that when the time comes, we will be in such a position that the problem of meeting competition will not be insurmountable. Following out this policy, as I have stated already, our annual interest charges have been greatly reduced, and I might say that these charges for the current fiscal year will be more than half a million dollars under the figures of two years ago—this in addition to interest on bank loans, which have been eliminated.

"Many expressions of opinion have been presented at one time and another with regard to conditions which may prevail after the war, and while it is given to no man to definitely foretell the course of events, I feel, as far as the demand for materials such as we manufacture is concerned, that we may look to the future with confidence. It is inevitable that replacements and renewals, and replenishments of stocks throughout this country and abroad, which have been given second place during the urgent call for war materials, must, when conditions again become normal, culminate in a strong demand for products of all kinds. We should, however, be prepared for adjustments immediately following the declaration of peace, which may possibly result in a period of lessened industrial activity more or less extended. Nevertheless, the underlying need will seek to assert itself at the first favorable opportunity, and will sooner or later force merchants and consumers into the market.

"These problems, as I have said before, belong to the future. As for the present, I am happy to report that we are booked up in steel products to the end of the calendar year, in addition to which our shell steel output for the first six months of 1918 has been disposed of."

After the presenting of the president's address, H. Gordon Strathy asked if it were not possible for the shareholders to have more than one statement a year. To this the president replied that he could promise a statement of the output of steel each month, but that it was rather difficult, owing to the fact that a varying amount of business was done during the different seasons of the year, to issue satisfactory quarterly or half yearly reports of earnings.

Asked if it would not be possible to pay a quarterly dividend on the subsidiaries' preferred stocks, instead of half yearly, the president replied that the right to do that would have to come from the shareholders. That and the question of earning statements would not be lost sight of, and he personally would give them serious consideration.

Most of the Montreal directors were present and among the out of town directors were Hector McGinnis, K.C., M.P., Halifax; Brig.-Gen. Sir Henry Pellatt, Toronto; Lt.-Col. the Hon. F. Nicholls, Toronto; W. D. Matthews, Toronto, and Brig.-Gen. the Hon. James Mason. Other shareholders present were: M. E. Williams, F. W. McAnulty, A. Michaud, S. L. Herman, Geo. H. Bishop, W. R. Miller, C. W. Lindsey, P. E. Brown, Thos. Tate, F. J. Lewis, A. P. Frigon, R. B. Verner, A. LaRose, J. B. Clearihue, J. J. M. Pangman, L. McIsaac Sprackman, Dr. E. E. Simard, G. D. C. Dobbin, Dr. E. M. Hill, J. Gow, J. N. Cote.

CANADIAN GOVERNMENT RAILWAYS STATEMENT

A SURLPUS of earnings over operating expenses amounting to $1,137,713 on the Intercolonial Railway System and a deficit of $1,966,626 on the National Transcontinental Railway during the past fiscal year, were reported by Hon. Frank Cochrane in his annual statement to the House of Commons on June 12, with reference to the operations of the Government railways. That system now comprises 4,063 miles of railway made up of the Intercolonial, 1,562 miles; Transcontinental, 2,009 miles; Prince Edward Island Railway, 275 miles; International Railway, 112; St. John Valley, 105.

The earnings of the Intercolonial, Mr. Cochrane said, were abnormally low during the four winter months because the road was engaged in hauling war materials and had to embargo many lines of freight which paid higher rates. Moreover, on that line, the operating expenses were augmented by increased materials and supplies and increased cost of coal, materials and supplies and increased wages and also by the unfavorable weather conditions and the congestion of traffic at Montreal.

Earnings amounted during the year to $16,802,290, and operating expenses to $15,664,577, leaving a surplus of $1,137,713, as compared with $1,517,295 in 1915-16. The surplus, the Minister of Railways said, would be absorbed by the equipment renewal account.

On the Transcontinental, earnings amounted to $5,916,550, as compared with $3,758,387 in 1915-16, and operating expenses were $7,883,177, as compared with $4,410,528. The deficit, Mr. Cochrane stated, was due to the comparatively small amount of traffic offering for that railway, to the fact that trains not warranted by business had to be established and to the necessity for maintaining the road at the standard of other transcontinental lines.

Operating Expenses

The operating expenses of the entire Government Railways System for the fiscal year ended March 31 last, were $24,645,433, as compared with $17,797,061 in 1915-16; the earnings were $23,465,565, as against $18,373,143. The deficit for the whole system in 1916-1917 was, therefore, $1,179,867. The total number of passengers carried on the system was 5,673,796, including 277,155 men of the military and naval forces, who traveled in 443 special trains.

The total estimated cost of the work on the Prince Edward Island car ferry terminals and railways leading thereto, is $2,910,000, of which $2,600,000 has been expended.

Rails have been laid on the Hudson Bay Railway to Mile 232, which is the second crossing of the Nelson River. Of the 92 miles remaining between the bridge and Port Nelson, all is graded but 11 miles. The bridge across the Nelson will be completed this summer and the rails will be laid into Nelson this year. Work has been slowed up on the Nelson harbor owing to war conditions. The estimated cost of railway and harbor work is $26,000,000, of which $18,175,000 has been expended—$12,565,000 on the railway and $5,610,000 on harbor terminal work.

The estimated expenditure on the Welland Ship Canal is $50,000,000, and of this about $13,000,000 has been spent. Work has been suspended on the canal owing to war conditions, but it is in such condition that no damage is anticipated during the period of suspended operation.

The Trent Valley Canal is practically completed between Lake Simcoe and Lake Ontario. The section to connect the Severn River with Georgian Bay has not yet been placed under contract.

Train Braking on Quebec Bridge.—The long suspended span of the Quebec bridge, 640 feet between pins, will be subject to a sudden movement, over the 17 in. leeway provided, when brakes are applied to a high speed train passing over it. In order to restrain this influence a traction brake is provided at the end of the cantilever arms. This brake is made up of a series of plates that slide between each other and are kept in contact by a set of car springs under a constant compression. Every alternate plate is fixed by a pin at one end to the horizontal piece of chord at the end of the cantilever arm and has a slotted hole at the other end to allow the necessary motion on the pin, which fixes the remaining sliding plates to the suspended span. These remaining plates are slotted in a similar maner, so as to allow the same amount of motion on the pin connecting the first-mentioned plates to the cantilever arm.

Metal Planers, and Methods of Production Employed*

By Charles Meier **

High-speed steel and the desire to obtain the highest possible speeds in both directions have rendered changes in planer design imperative. One of the objections to speeding up has been the difficulty encountered at the reverse. This was at first partly overcome by lightening the driving pulleys, and has now been satisfactorily met by the reversible motor drive. To eliminate fatigue of the operator and save time, rapid power traverse is now generally used. This is quite a departure from the standard construction in which the heads are hand operated. Comparatively little thought has been given to handling planer work.

THE problem of providing the increased speeds and power to develop the possibilities of high-speed steel and to meet the increasing necessity for greater production has been a comparatively simple one in such machines as lathes, drilling machines, boring mills, milling machines in which the cutting is continuous and the motion of the tool is in one direction only. In this type of machine it has meant merely adding power and strengthening parts.

The speeding-up process introduces, however, a vastly different problem in such machines as slotters, shapers and planers, in which the cutting is not continuous and which have a return motion of the tool. The principal limitations of machines of this class, especially the planer, are twofold, first, the inertia of the moving mass at the moment or reverse; second, the speed at which the tool enters the work. The problem of overcoming these limitations has had the attention of quite a number of engineers, and while considerable progress has been made the complete solution does not seem to have been reached.

Evolution of Planing Machine

The evolution of the planing machine has followed along the lines of increased table speeds. The earlier demands were all for a higher return speed, in the belief that great savings could be effected by reducing the idle time consumed in the return of the table. It next followed that further gains could be made by increasing the cutting speed, owing to the fact that this part of the cycle consumed the greater part of the time involved. The advent of high-speed steel can be credited largely with the marked advance in this part of the development. After fairly high speeds in both directions were obtained there came the demand for variable cutting speeds. It soon became a recognized fact that to operate a planer having only one cutting speed was both wasteful and detrimental to the best methods of increased production.

This constant change of conditions and the desire to obtain the highest possible speeds in both directions, led to serious difficulties for which a change in design became imperative. One of the objections to the speeding-up of the planer was the difficulty encountered at the reverse, namely, the inertia of the moving parts. Several tests were conducted which established the fact that the greater part of the trouble was caused by heavy machine pulleys and their high speeds. Various types of magnetic, pneumatic and mechanically operated clutch drives were designed in which the pulleys were not reversed. Our experience with these drives was that they developed the objectionable features inherent to friction clutches, namely, the slippage and wear which takes place before the parts are properly engaged. The most successful of these types was the pneumatic clutch. A few planers were built which embodied heavy springs to overcome the shock at reversing. We designed one machine in which these springs were added into the driving gears, and in another machine the table rack was made floating and held in place by two heavy springs at either end. These designs did not prove satisfactory, owing to the variable pressures while under heavy or light cutting. Also the springs had very little effect at the moment of reverse.

Length of stroke, ft.	Time table was running, min.	Number of cutting strokes with c.i. pulleys, weight 56 lb.	Number of cutting strokes with aluminum pulleys weight 20 lb.	Number of strokes gained	Theoretical number of strokes	Per cent efficiency of aluminum pulleys

TABLE 1 TEST ON 30 x 30 x 14 FT. "CINCINNATI" PLANER TO SHOW GAIN IN STROKES, AND EFFICIENCY OF ALUMINUM DRIVING PULLEYS OVER CAST IRON DRIVING PULLEYS. CUTTING SPEED 40 FT. RETURN SPEED 90 FT.

Aluminum Alloy Driving Pulleys

It seemed that none of these arrangements quite met all conditions, and to overcome the difficulties in the standard belt-shifting machines experiments were conducted with lighter driving pulleys. A step which marked quite an advance in this direction was the use of an aluminum alloy for the pulleys instead of cast iron, so that a decided gain was made in the number of cutting strokes owing to the fact that less time was consumed in the reverse. Table 1 gives results of a test made on a 30 x 30 x 14-ft. planer and gives good idea of the gains effected by the use of aluminum pulleys. These pulleys were also found to effect quite a saving in power. Table 2 shows a test

TABLE 2 TEST OF 76 x 62 x 32 FT. "CINCINNATI" PLANER WITH CAST IRON AND ALUMINUM PULLEYS.

*From paper read at A.S.M.E. Spring Meeting, May, 1917.

**Of Cincinnati Planer Co.

made on a 76 x 62 x 32-ft. planer, in which the saving in power was about 25 per cent.

Individual Electric Motor Drive

The subject of individual electric motor drive for planers has received considerable attention in the past few years. One type of drive which has been successfull developed in the variable-speed drive. This consists of a 2 to 1 variable-speed motor coupled direct to the top driving shaft of the planer. The speed of this motor is controlled by two separate sets of resistance which are automatically operated by a master switch connected to the shifting mechanism of the planer. The cutting speed can be varied from 25 to 60 ft. per min., while the return speed may be varied if desired without affecting the cut. The controller handles are set to a predetermined speed before starting. The planer is operated in the usual manner from the tumbler, and the master switch automatically varies the speed of the motor at each reversal. This type of drive has the desirable feature of eliminating the mechanically operated speed variators and is quite simple in operation. It provides a very flexible arrangement when variable speeds are desired. This is especially true on the smaller sizes of planers.

Reversible Motor Drive

The motor is an adjustable-speed unit, having a speed range of 1 to 4, so that a large range of cutting speeds from 25 to 60 ft. per min. can be obtained. A double set of resistance is provided making it possible to vary either cutting or return speed independently of the other. This arrangement has also simplified the problem of variable speeds in connection with this drive. The operating mechanism is handled in exactly the same manner as is the standard belt-shifting-type planer, so that no complications are encountered by the operator. Two predominating features in this type of drive are the total absence of belt slippage under heavy cutting and the lower peak loads at the moment of reverse. Table 3 shows the importance of these two features over the belt drive. It can be said that the reversible motor drive as applied to-day furnishes all that can be desired of an efficient planer drive.

	Single belt drive	Double belt drive	Pneumatic clutch running at 200 r.p.m. on cut and 600 r.p.m. on return	Poeumatic clutch running et 70 r.p.m. on cut end 200 r.p.m. on return	Direct-connected electric motc having cutting-speed range of more than 2 to 1 and a total speed range of 4 to 1

TABLE 3 TEST MADE BY GENERAL ELECTRIC CO. ON 60 IN. x 72 IN. PLANER.

The study of fatigue of the operator and easy control of the machins is receiving quite a lot of attention in almost every machine operation, and there is no doubt but that great possibilities in this direction exist in machine-tool construction. Power operation of heavy machine parts seems to have found a permanent place in the construction of all classes of machinery. There is an increasing demand for elimination of lost time between cuts, and this feature has also found its way into the design of planers.

Rapid power traverse is now being generally used in manipulating planer heads in all directions. This is quite a departure from the standard construction in which the heads are operated entirely by hand. Experience has demonstrated that the new practice eliminates a considerable amount of wasted time throughout the day, and is a decided help to the operator as it saves him from undue exertion and fatigue.

Production

As a general rule comparatively little thought is given to the subject of handling work on the planer. If the same amount of time and study were devoted to providing jigs and fixtures for the planer that is given other machining operations, the saving in time would be astounding. In the majority of cases a careful analysis will show that the machine itself is engaged during only a small portion of the total time taken to complete the operation. The balance of this time is lost in setting the work, measuring for roughing cuts, fitting for finishing cuts, and changing and grinding tools.

In planers, as in any other machines, we depend on the operator to a large extent for the best results. Invariably the question of chucking work on a planer is left to his discretion, and he proceeds to the best of his ability with the equipment allotted him, which usually consists of an assortment of bolts, clamps and blocks instead of jigs and fixtures.

I have found innumerable cases in which the chucking time alone almost trebled the cutting or machining time. Adding to this the time lost in changing tools and measuring work, we find as an average that the total actual time required to complete a piece of work is from 4 to 5 times the theoretical time necessary to plane the piece, the theoretical time being based on the number of square inches to be placed and the cutting and return speed used.

FIG. 1. EXAMPLE OF TIME-SAVING JIG ON PLANER.

It is not surprising to find that where

time studies are conducted frequently a saving from 50 to 200 per cent. in time is effected, this through the elimination of wasted chucking and measuring time.

In the greater number of cases a holding fixture with screw adjustments can be devised so that it is only a matter of dropping the piece into this fixture and applying the clamps, which should be part of the fixture. Hardened steel plugs can also be incorporated into the jig to indicate the various heights and angles of the piece without the use of scales or referring to a drawing. These are a great help, especially in the roughing operation. Gang tools and double-end cutters also assist greatly as they save considerable time in getting correct sizes without measuring.

As an example of what this jigging up has meant in one instance, Fig. 1 shows a shortwall coal-cutting-machine main frame being planed. For quite a while these frames were planed in the old-fashioned way by clamping and stopping them on the planer table. The average time required for planing with this method was 28 hours. Since the proper jigs and fixtures have been provided, these frames are now being planed complete in 4 hours. On this jig bosses are planed on which hardened blocks are set for setting the tools.

Another very good result obtained by time studies is the planing of locomotive cylinders complete in one setting. As a general rule these cylinders are planed one at a time and several settings are required. After a careful study, fixtures were provided which were so arranged that four surfaces could be planed at one time, using four tools for the cutting instead of only one. The saving in time on a pair of these cylinders was about 100 per cent.

The building of high-grade planers has established itself as an important factor in the machine-tool building field. Many users seldom realize that, unlike smaller machine tools, the building of a planer requires a more extensive equipment of machinery, as well as a large number of costly fixtures and measuring instruments. The planer is necessarily a large and expensive machine, and proportionately larger returns are obtainable from it than from smaller machines owing to the higher expense or burden charged against it. The planer, therefore, should receive special attention from the time-study department.

IRON AND STEEL IN CANADA, 1917

THE Mines Branch of the Department of Mines has received from the producers complete returns of the production of pig iron in Canada, and with the exception of three small plants, complete return of the production of steel ingots and castings during the first three months of 1917.

The total production of pig iron during the three months was 276,777 short tons, or an average monthly production of 92,259 tons, as against an average monthly production throughout 1916 of 97,438 tons.

Furnaces were in blast at Sydney, and North Sydney, Nova Scotia; Hamilton, Port Colborne, and Sault Ste. Marie, Ontario, and a small electric furnace was operated at Orillia, producing pig iron from scrap steel. The blast furnace at Deseronto was idle throughout the period.

The total production of steel ingots and castings during the three months was 403,880 short tons, or an average monthly production of 134,627 tons, as against an average monthly production of 106,268 tons during 1916.

The monthly production, exports and imports, 1916 and 1917, are shown in the accompanying tables:—

ELECTRICAL DRIVE FOR ROLLING MILLS

By O. C.

THE driving of rolling mills is one of the most difficult problems the electrical engineer has ben called upon to solve. He has accomplished it quite successfully in a number of cases. The problem was an exceedingly difficult one even for the steam engineer; and the difficulty arises from the very quickly changing character of the load. Before the billet is entered between the rolls the only work the steam engine or the motor has to perform is the very trifling amount required to turn the rolls, along with the engine or the motor itself; immediately the rolls take hold of the billet the power rises to a maximum, which may be several hundred or several thousand horse power, according to the size of the rolls and the character of the work they have to perform. Immediately the billet emerges from the rolls on the other side, the whole of the power previously absorbed is set free, the engine or the motor now being required to furnish only the trifling power absorbed by the friction of the apparatus itself. The period of rest, however, as is well known, is very short, only sufficient to allow of the billet being re-entered between the rolls for the return pass; and immediately it is again entered and the rolls have gripped it, the power rises to a maximum, though usually not quite so high as the first pass; and this alternate no-load and full-load goes on until the billet has made all its passes; the power required being less at each pass, but being required each time for a longer period.

The first difficulty that confronted engineers in solving the problem was the question of meeting the requirements of the generating station. It is a very serious matter for any generating station to have sudden demands for very large currents, and still more for the station to be subject to the violent fluctuations of these demands. Most generating stations impose a limit upon power customers of the amount of current they may call for at any instant; and the reason is the outflow of a very large current from the generating station at any instant, lowers the pressure of the supply service for the time until the devices provided for meeting increased demand have time to operate. With the increased demand for current for power purposes, central station engineers have been gradually able to keep the lighting service free of the power service, and so they are able to allow larger calls on the power service than previously. But even where the power service is independent of the lighting service, the demand resulting from the insertion of a billet in the rolls of a large mill, would seriously lower the pressure of the service to all the other motors.

With modern methods of electric power distribution also over large areas by the aid of three phase alternating currents, heavy demands for current lead to somewhat serious induction troubles. The difficulty has been met in the same manner as with the colliery winding engine; in fact, the apparatus employed for driving rolling mills is a development of the electric winding engine. The fly-wheel again performs the useful office of absorbing the power that would be running to waste in the intervals between the different passes, and giving it out to aid the current taken from the service during the heavy starting and acceleration period. The interposition of the fly-wheel protects the electric supply service from the heavy demand that would otherwise be made upon it during the early portion of each pass. The full power released by the emergence of the billet from the rolls is not available to assist during the starting period, and therefore the economy to the user will not be so great as if he were allowed to take all the current he required directly from the service. On the other hand, if a central station did allow such an arrangement, it would be obliged to make higher charge for the current, and the cable employed to deliver the current to the rolling mills would require to be very large, or there would be a considerable lowering of the pressure at the motor, in addition to which, the drive would not run as sweetly as it does under existing arrangements.

PROBABILITY OF SHOP BUILDING STANDARDISATION

By D. Street.

SINCE the remarkable innovation of the standardisation of ships is now being seriously discussed, it seems not unreasonable to suppose that a similar improvement may yet embrace shop buildings. These may in the near future be standardised under the aegis of the economical intensive industry that must certainly follow the war. In England the way has been well prepared and smoothed by the work of the Engineering standards Committee, who have standardised all the structural materials required. It may not be a long step from the materials to the buildings. It would merely transfer the work of design from the architect who may often have a superficial acquaintance with industrial requirements, to the people who make a speciality of such buildings. A great deal of tedious independent calculation could be saved, and calculation for a given kind of building of given proportions made for all parties. The basis of these are available in books of sections for various loadings, they would only have to be extended to the actual buildings. It would be merely an extension of the principle which is regularly utilized by builders of machine tools, cranes, automobiles, and so on.

The requirements of a firm being known, a standard design already being worked out, exactly or approximately suited to the firms requirements, could be submitted without the delay entailed by getting out complete new plans. The work could be put in hand at once, and the building completed almost before the plan could be prepared by the general architect. Something of the kind is being done by firms who supply the steel skeletons for factories. It would only be necessary to extend it to include foundations, floors, lighting, etc. Alternative plans might be available for walls of masonry or concrete or corrugated sheet, for side windows or roof lights, for single floor buildings or storied buildings, to suit the varied requirements of firms. This kind of thing would grow, and the standard patterns multiply. Already one is aware, that when firms erect new buildings they now often adopt designs which by their similarity are pointing the way to standardisation. The extensions of existing buildings would also be greatly facilitated by such a system because it would only involve additional units already standardised. A few weeks would suffice for carrying out directions or extensions which normally occupy the same number of months. The actual cost would generally be less.

A Rope Drive Puzzle.—In connection with rope driving the question is sometimes asked: "Why do some ropes revolve in the groove, while others do not?" In a paper on "Rope Driving," read recently by R. Edward Hart before the members of the Bradford Engineering Society, the author says this question has never been satisfactorily answered. It is reassuring, however, to learn from the paper that whether ropes revolve or not has very little to do with their longevity, as it is easy to point to both types which have worked well for many years. Some people, says the author, imagine that when a rope begins to revolve it is rapidly rubbing itself away; this is quite an erroneous view of things. As a matter of experience, the ropes which have the longest life are, in the majority of cases, quite circular in section. And when the ropes have been running for any length of time, it is always easier to tighten a round rope which has been worn evenly all over its surface than to attempt to resplice a rope which has worn V-shaped and taken all the wear on its two sides only. Some engineers prefer ropes to revolve, because they affirm that there is less frictional loss whilst leaving the groove with a round rope than with a V-shaped rope, maintaining that it partakes more of the nature of rolling friction.

Walking through the village street one day, the widowed Lady Bountiful met old Farmer Stubbs on his way to market. Her greeting went unnoticed.

"Stubbs!" said she, indignantly. "You might at least raise your hat to me!"

"I beg your pardon, m'lady," was the reply, "but my poor wife ain't dead dead more'n two weeks, and I ain't started lookin' at the wimmen yet!"

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

12-IN. ROTARY SURFACE GRINDING MACHINE

THIS rotary surface grinding machine has been designed especially for the rapid and accurate finishing of flat surfaces, and has a capacity for work up to twelve inches in diameter, either a single piece or a number of smaller pieces as desired.

It is very compact and massive in construction, with large bearing surfaces, these features being necessary for the rapid and efficient removal of stock and the securing of surfaces with a high finish.

The design is entirely self-contained, requiring but a single belt from the main line, and thus doing away with all overhead countershafts and a multiciplity of belts.

The machines may be furnished motor driven if desired, the motor being located on a bracket at the rear, making the motor-driven machine also self-contained and providing in this way a very compact arrangement.

The grinding wheel is 12 in. dia. by 1 in. face, and is mounted in a very rigid wheel slide having two flat ways with taper gib adjustment. The bearing surfaces are unusually large and are carefully protected from grit and dirt. The belt pull on the wheel slide is downward, thereby adding to its stability. The grinding wheel spindle is large in diameter, and is furnished with a taper bearing running in a bronze bushing at the grinding wheel end and is carried in ball bearings at the rear end. The spindle, therefore, requires but one simple endwise adjustment for the taking up of all wear.

Ample power is provided by the use of large belts and the machine is able to remove large amounts of stock, as well as as producing a high quality of finish; the amount of stock which may be removed at one cut is only limited by the ability of the wheel to stand up under the work. In this machine the grinding is done by the periphery of the wheel, which is especially desirable if accuracy is desired, and a high quality of finish is important. Feed lines and radial scratches in the work are eliminated by using the grinding wheel in this manner.

The machine is provided with automatic feed for the wheel slide, so that the grinding wheel will automatically traverse over any portion of the chuck desired. A pilot wheel is provided for hand feed which might be preferred on certain classes of work, being disengaged at any time when the automatic feed is in use.

The machines are regularly equipped with a 12 in. Heald magnetic chuck, but they can be furnished if desired with a 10 in. or an 8 in. magnetic chuck; or if the work is not adapted to be held on magnetic chucks to the best advantage, three jaw chucks or face plates with holding fixtures can be substituted. The chuck is mounted on a vertical spindle so arranged that no adjustment for wear is required, this being automatically taken up. The chuck spindle is carried inside a sleeve which is raised or lowered by a threaded nut running on ball bearings, making it easy to adjust the chuck to any position required to suit the work being ground.

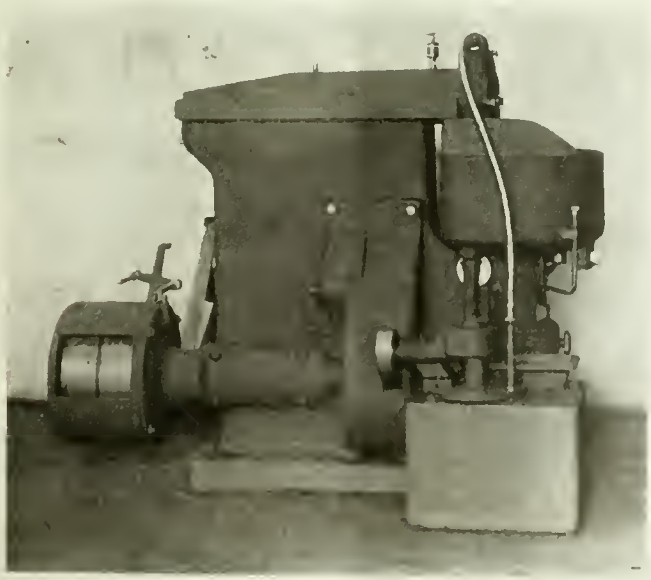
The work is fed to the wheel by means of a hand wheel with graduated dial. An automatic vertical feed is regularly furnished, as this is a desirable feature when there is a considerable amount of stock to be removed, or when it is desirable to have one operator handle more than one machine. The chuck spindle is provided with an angular adjustment so that the machine will grind concave or convex surfaces up to an angle of five degrees. This feature is very desirable when grinding saws or cutters, and is also valuable in providing adjustment to enable the machine to grind absolutely flat surfaces even after long service.

The machine is regularly equipped with pump, tank and water guards and all connections for wet grinding. A liberal supply of water is delivered at the grinding point, and the guards are so designed as to thoroughly protect the operator and keep the water within the machine.

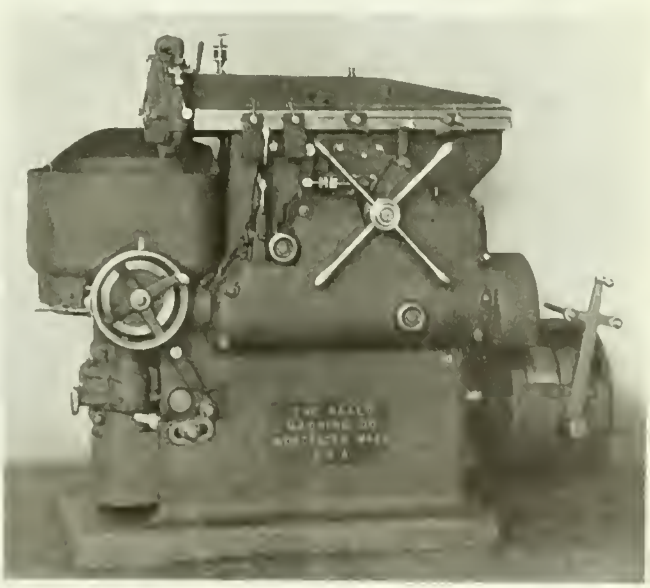
Particular attention might be called to the design of the gear box on the front of the machine which contains practically all of the mechanism for driving the chuck and the wheel slide at their different speeds. All the parts in this unit are easily accessible and the very simple and compact arrangement of this unit adds largely to the efficiency of the machine. Four changes of speed for the chuck and four changes of speed for the wheel slide are instantly obtained by simply turning a hand wheel; the chuck speeds and the wheel slide speeds are independent. This machine is built by the Heald Machine Co., Worcester, Mass.

AUTOMATIC TAPPER AND BENCH DRILL

AN AUTOMATIC tapping machine which also combines the functions of a bench



REAR SIDE OF SURFACE GRINDER, SHOWING DRIVE FROM PULLEY SHAFT TO GRINDING WHEEL SLIDE, ALSO WATER PUMP, ETC.

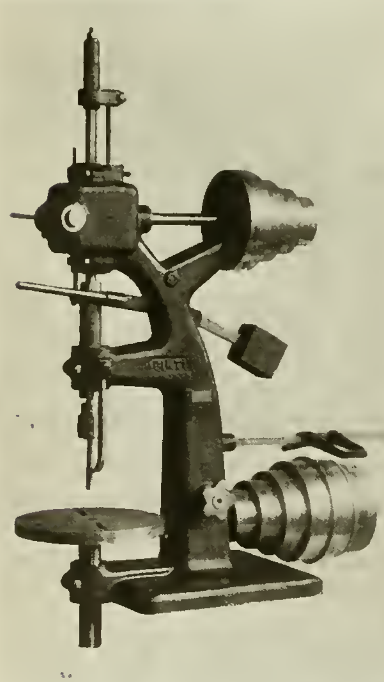


OPERATING SIDE OF SURFACE GRINDER SHOWING HAND FEED TO GRINDING WHEEL SLIDE AND VARIOUS CONTROL LEVERS.

drill is shown in the accompanying engraving, being built by W. H. Simons & Co., Cincinnati, O. It is of compact and rigid design, with four-step cone pulley drive from self-contained countershaft, giving spindle speeds of 150, 250, 390, and 600 dev. per min. It drills on taps to the centre of a 12 in. circle. The maximum distance from spindle to table is 10½ in., the vertical adjustment of spindle being 3¼ in., and of the table, 5 in.

The spindle is equipped with a load for any desired pitch, 16, 18, 20, and 24 thread leads being standard equipment. The clutch and reversing mechanism can be set to run the tap to any desired depth reverse automatically, and, after the tap clears the work, the spindle stops automatically. All contact points throughout are hardened.

A belt tightening device is provided, being operated by a star grip on the side of the column, so that the cone belt can be adjusted to any tension desired. Bronze bearings are furnished throughout, and the pulleys on the lower shaft



COMBINED BENCH DRILL AND AUTOMATIC TAPPER.

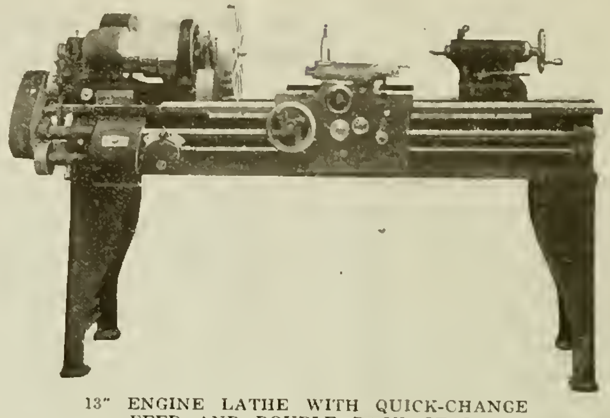
are bronze bushed. The tapping capacity of the machine is ⅜ in. in cast iron, with a drilling capacity of ½ in. in the same material.

13 IN. ENGINE LATHE

THE lathe illustrated herewith has been placed on the market by the Philip Smith Mfg. Co., Sidney, O. It is of entirely new design and possesses ample power for the rated swing.

The headstock is of the solid full-webbed type; its rigidity and close adjustments prevent chattering on heavy cuts. The front spindle bearing is 4 x 2⅜ in., and the rear, 3 x 1 13/16 in., both self-oiling, while a 1 15/16 in. hole is provided through the length of the spindle. The spindle is made of 50 point carbon crucible steel, ground to size and fitted in phosphor bronze bearings.

The bed is wide and deep, with heavy walls and large box girders. It is fitted with a carriage having a bearing 18 in. long on the vees; the bridge is 7¼ in. wide and tee slots are provided for clamping special work. The compound rest is ususually large and rigid, is provided with taper gibs, and graduated for angular work.



13" ENGINE LATHE WITH QUICK-CHANGE FEED AND DOUBLE BACK GEAR.

The apron is a one-piece casting, all bearings being integral; steel gears are used and all studs are hardened and ground. The half nuts have safety device to prevent unintentional engagement and graduated dials are on both cross-feed and compound rest. screws.

Quick change feed mechanism provides four changes of feed. All gears are guarded, one piece steel rack is fitted, all sliding surfaces scraped to a bearing and all cylindrical parts ground to size. Standard equipment consists of compound rest, follow rest, steady rest, double friction countershaft and wrenches. Special equipment includes drawn-in chucks of ⅝ and ⅞ in. capacity, taper attachments, automatic stops, chasing dial, etc., and bed lengths of 8 and 10 feet.

The machine with 6 ft. bed has specifications as follows: Swing, over bed, 13¼ in.; over carriage, 8¼ in.; between centres, 35 in.; centres, Morse taper No. 3; cut threads, English, 4 to 20, metric, ½ to 8 mm.; spindle speeds, 18, max., 600 min., 27 rev. per min.; net weight, 1,250 lbs.

AUTOMATIC MUTIPLE PLUNGER PRESS

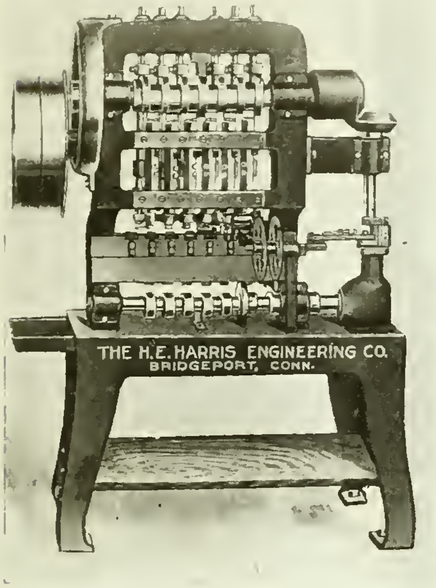
SHEET metal work, which embraces the manufacture of such articles as eyelets, snap fasteners, pencil tips, primers, percussion caps, thimbles, buttons, ferrules, grease cups, and containers for drugs and toilet preparations, is produced successfully by the employment of mutiple plunger presses of the type shown in the accompanying illustration. Rapidity of operation is a feature of these machines, the output ranging from 35,000 to 80,000 pieces per day of ten hours inclusive of time for repairs, setting up, sharpening tools, oiling, replenishing stock and other regular interuptions during running. The large variation in output covers all classes of work, the output for any particular article depending on the kind of material used, gauge, and dimensions of finished article. The actual speed varies from 65 rev. per min. to 150 rev. per min.

The type of machine illustrated will automatically cut a blank from sheet metal and carries the work along to the successive operations under the other plungers, completing the part and performing such operations as piercing, forming, drawing, trimming, light

SPECIMENS OF WORK PRODUCED ON MULTIPLE PLUNGER PRESS.

stamping or embossing, etc., producing complete parts automatically from the sheet stock without manual handling.

While the basic principle of the machine has been in use for many years, several improvements have been made in



MULTIPLE PLUNGER PRESS FOR CONTINUOUS PRODUCTION OF SHEET METAL PARTS.

the last two years. The frame is off set at the left hand side, and provision is made for an extra die and for a double punch to be carried by the last plunger. In this way the press performs one more operation than the number of plungers. This is a distinctive feature, for if it becomes advisable to add an additional operation, such as stamping, a name or trade mark, or any other operation which becomes desirable after first planning, the provision for taking care of it in the machine is thus provided. All the operations are simultaneous; that is, with each revolution of the cam shaft, each one of the plungers performs an operation on the parts which are going through the press. The speed of operation and methods of performing the work do away entirely with annealing the parts between operations. The weight of the machine and the throw of the cam and other details are arranged to suit the parts to be manufactured in the press; likewise, the number of plungers are varied to suit the number of operations required to manufacture the piece.

The machine consists of a heavy main frame carrying a number of press plungers operated by a cam shaft which determines the timing and the throw of such plungers. These plungers carry the different punches for blanking, embossing, piercing, drawing, etc. The bolster fitted on the bottom part of the main frame, holds the different dies to suit the punches and carries the transfer slide.

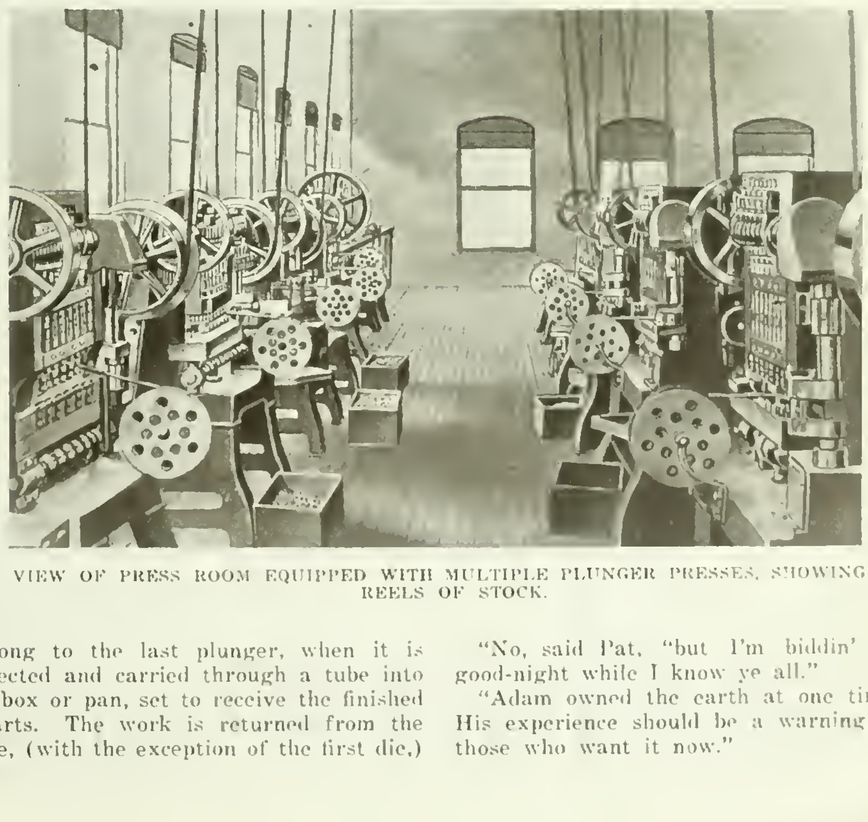
The plungers are returned to their upward position after the operation of the punches upon the part by the same shaft, but with a separate set of cams. This is done by the adjustable horizontal members shown above the cam shaft, and may be seen between the cam shaft and the upper cross member of the frame, and connected to the plungers by means of the vertical lifting rods at the back.

The machine operates as follows:—The metal which is in the strip form and coiled, is placed on the reel in front, passes through a lubricating pad and through a stripper over the blanking die to a feed roll mechanism in the back. This feed roll mechanism is operated by the intermittent ratchet, timed so as to co-ordinate with the operation of the press. While the strip stock is at rest in this position, the first plunger blanks out the piece and carries it through the die to a pocket in the transfer slide, a reel at the back reeling up the scrap stock after it leaves the feed rolls. The transfer slide moves from right to left by the action of the vertical crank shaft, this movement being equal to the center distances between the plungers. This action moves the blanked piece in the pocket in the transfer slide along to the second plunger which carries the forming punch, and the second operation is performed by the punch in the second plunger, drawing the blanked piece through the transfer slide, and into the first forming die. The transfer slide now moves back from left to right, into its first position, so that it can move again from right to left, carrying the second blanked piece from the first plunger to the second position, and at the same time carrying the cupped piece from the second position to the third position.

This operation of carrying on to the next plunger, is repeated at each stroke of the press, until work has been carried along to the last plunger, when it is ejected and carried through a tube into a box or pan, set to receive the finished parts. The work is returned from the die, (with the exception of the first die,) to the transfer slide where it drops into a pocket, by vertical ejector plungers, operated by the lower cam shaft, which is geared to operate in synchronism with the upper cam shaft, through the medium of mitre gears on the two cam shafts, and the vertical crank shaft. This will be seen in the illustration at the right of the machine. These lower plungers push the work up out of the die at the proper time, into the fingers of the transfer slide.

The transfer slide is fitted with these carriers or fingers, for each station, except the first station. These take hold of the piece like the thumb and index finger of the person's hand, and are the means of holding the parts when transferring to the succeeding operation. The machine is thus fully automatic in its operation, the attention of the attendant is only necessary to keep the stock reel supplied with stock, and to remove the boxes of finished work and small piercings, if any, replacing them with empty boxes, and one attendant can care for a dozen or more machines.

These machines are the product of the H. E. Harris Engineering Co., Bridgeport, Conn., the most general sizes being with four, six and seven plungesr..



VIEW OF PRESS ROOM EQUIPPED WITH MULTIPLE PLUNGER PRESSES, SHOWING REELS OF STOCK.

Mr. Flanagan attended a christening where the hospitality of the host knew no bounds. In the midst of the celebration Flanagan rose up and made the rounds of the company, bidding each a profound farewell.

But, Pat, man," objected the host, "you're not goin' yet, with the evening' just started?"

"No, said Pat, "but I'm biddin' ye good-night while I know ye all."

"Adam owned the earth at one time. His experience should be a warning to those who want it now."

SOME FEATURES OF OUR MINERAL RESOURCES DEVELOPMENT

As was to be expected, the pronounced manufacturing activity—metal-working and otherwise, which marked the year 1916, in Canada, was not without a parallel in her mineral recovery. The total production of marketable coal amounted to 14,461,678 short tons, valued at $38,857,557, as against 13,267,023 short tons valued at $32,111,182 in 1915, or an increase in quantity of 9 per cent., and in value of 21 per cent. The general industrial situation necessitated more and greater freight movement, thereby increasing the demand and stimulating production, particularly in Western Canada.

The output of oven coke during 1916 was 1,448,782 short tons, while that of 1915 was 1,200,766 short tons. The 1916 returns show a recovery of 67.9 per cent. of the total coal charged as compared with 64.7 per cent. in 1915. It should be noted that for the 1916 coke production, 1,501,835 short tons were of domestic origin, and 633,076 short tons were imported.

Pig-iron production during 1916—exclusive of ferro-alloys, amounted to 1,169,257 short tons, valued at $16,750,903 as against 913,775 short tons valued at $11,374,199 in 1915. The 1916 output of pig-iron established a record, the year 1913 with 1,128,967 short tons being our previous best. The value of the former as compared with the latter is naturally much higher, due to the increased price obtainable, in which connection, at the prices which have been ruling during the present year so far and likely to be well maintained during the ensuing six months, we may look for not only still further increased output, but a total value several millions of dollars higher comparatively.

Iron ore operations were almost wholly confined during 1916 to the Helen and Magpie Mines of the Algoma Steel Corporation, the total shipments being 339,600 short tons valued at $814,044 as compared with 398,112 short tons valued at $774,427 in 1915. Shipments of iron ore from Wabana Mines, Nfld., to Cape Breton, N.S., by the Dominion Steel Corporation, and Nova Scotia Steel & Coal Co., totalled 1,012,060 short tons. In 1915 802,128 short tons were shipped to Cape Breton and 66,323 tons to England.

The production of copper shows large increases during the past three years, due in great measure to the munitions demand. The comparative figures for Canadian ores mined in 1916 and 1915, showing returns from smelters of 119,770,814 pounds and 100,785,150 pounds respectively.

Nickel production totalled 82,958,564 pounds in 1916 as compared with 68,308,657 pounds in 1915, or an increase of 21½ per cent. That of Cobalt amounted to 841,859 pounds as against 504,212 pounds in 1915. The recovery of lead was less during 1916 than during 1915, the comparative figures being 41,593,680 and 46,316,450 pounds respectively. The enhanced price obtained per pound made an increase of 32 per cent. value in favor of 1916, however.

With the exception of a small production in experimental work, there was no recovery of zinc spelter, or refined zinc in Canada previous to 1916. The establishment of an electrolytic zinc refinery at Trail, B.C., and of a zinc recovery plant at Shawinigan Falls, Que., has placed the metallurgy of this metal in Canada on a similar basis to that of lead and copper. In 1916 it is estimated that Canadian zinc ores produced 23,515,030 pounds of refined metal as against 12,231,439 pounds in 1915. The major portion of the refining was performed in United States smelters in the former year, and all of it in the latter, but expectations are that when the figures for 1917 come to be compiled, the bulk of the refining will be credited to Canadian smelters.

From the data given, which treats only of the more prominent minerals and their reduction to a state which admits of their easy adaptation to the needs of our metal-working and kindred industries, so to speak, it will be apparent that research into and utilization of our natural resources have made gigantic strides during this war time, and bid fair to ensure our not only being able to extract expeditiously and profitably the mineral wealth, which we possess, but so deal with it as that only in manufactured form shall it go beyond our borders.

THE OUTLOOK

As an indication of the attitude of one of our most prominent industrial executives, the address of Col. Thomas Cantley at the recent annual convention of the Canadian Manufacturers' Association in Winnipeg, is worthy of close study and careful consideration.

The necessity of maintaining Canada's industrial organization at the highest possible level is apparent to the most casual observer of passing events and present conditions. A sudden collapse of manufacturing activity, say in Ontario alone, would be disastrous indeed, and the advocation of a sound fiscal policy to stimulate supplying "our own wants and produce in addition something exchangeable at a profit for such commodities as we do not grow or cannot produce," is worthy of generous response.

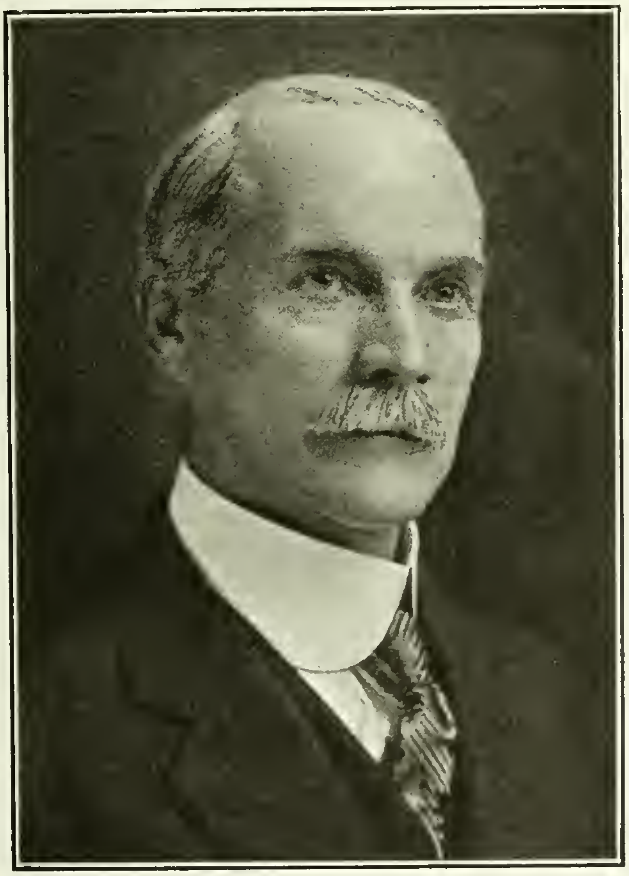
Complementary to the development of export trade, the desirability of a future Canadian mercantile marine is daily becoming more evident. The percentage of foreign-owned bottoms which in pre-war times prevailed in the St. Lawrence, should be looked on as utterly incompatible with the free, healthy growth of our Dominion world trade. Circumstances enabled the speaker to appreciate to the full the value of such an industry as shipbuilding to this country. Apart from its intrinsic value as such, the successful establishment of shipbuilding is sure to be accompanied by much activity in subsidiary lines.

The widely varying industries of the Dominion are well exemplified by the personality of S. R. Parsons, the newly-elected President of the Association. Paper and oil are somewhat of a contrast to iron and coal, but their prominence is little, if any, less. To attain success, such as Mr. Parsons has, betrays an ability far-reaching and persistent, and under his *aegis* the Canadian Manufacturers' Association may be expected to continue its good work of solidifying the efforts of our industrial interests, extending their scope and directing their policies so that the greatest good will result for the greatest number, nationally as well as individually.

INDUSTRIAL NOTABILITIES

S. R. PARSONS, president, British American Oil Company, Ltd., Toronto, was born in Port Hope, Ont., Aug. 4, 1854, son of William and Margaret (Trick) Parsons.

He received his education at Port Hope Grammar School, and migrated to Winnipeg as a young man, engaging in the wholesale stationery business as senior partner of Parsons, Bell & Co., which ultimately became merged with the Consolidated Stationery Co., Ltd., of which he was president for some years. His residence in Winnipeg extended over sixteen years and was terminated by an illness which necessitated a change of climate, resulting in his removal to Toronto and his establishing the present business in 1906.



S. R. PARSONS.

Mr. Parsons has been chairman, Ontario board of directors, Canadian Fire Insurance Co., since 1900; was elected chairman of the transportation committee, Canadian Manufacturers' Association for four successive years (1911-1915); elected second vice-president of the Association, 1915; first vice-president, 1916; president, 1917. Was also director of the Riverdale Business Men's Association for several years prior to 1913, and is still a member of that organization.

He has taken much interest in social, religious and philanthropic work in Toronto and was active in recruiting with the C.M.A. during the war. The Methodist Social Union received his guidance as a director for a number of years.

In 1882, Mr. Parsons married Annie Kate Helliwell, daughter of Rev. Thomas L. Helliwell, Winnipeg, their family consisting of three daughters.

Mr. Parsons resides at 139 Crescent Road, Toronto; is Independent in political creed, and Methodist in religion.

The General Market Condition and Tendency

THAT further advances in prices of steel products are assured is indicated by conditions prevailing in the steel market in the United States. Notwithstanding the present abnormally high level, prices continue to climb and no one knows when the present movement will stop. The shortage of steel is becoming more acute. Owing to the urgent demand for steel for war purposes, private consumers have to take material when they can get it, not when they want it. Warehouse stocks also are low, which makes the situation more difficult for the manufacturing consumer who used to rely on the warehouse for prompt delivery. The abnormal high price of pig-iron cannot help but ultimately affect prices of steel in addition to other influences. Several grades of pig-iron in the United States have now reached the $50 mark and are still climbing. The coke situation continues to cause considerable anxiety to both the steel mills and furnaces by reason of the difficulty of obtaining sufficiently large quantities. Prices are also very high. There is no noticeable improvement at present in the coal situation, although it is hoped that conditions may become more favorable in time. The scrap metal market is dull, the only material showing any real activity being heavy melting steel. Scrap prices are unchanged on the basis of last week's quotations. The demand for scrap with the already named exception is light. Prices of non-ferrous metals are unchanged from last week, but the markets for the most part are firm, due largely to the expectation of increased demand rather than to any active buying at the present time. There is a fair demand for machine tools for general purposes, but the market is inclined to be quiet.

Montreal, Que., June 18, 1917.—Industrial conditions are again emphatically reflected in the continued advance of pig iron and steel products. In addition to the higher cost of all raw materials, there is the possibility that an early shortage may develop in certain lines, when the full requirements of the American Government are announced, which may have the resultant effect of curtailing the output that can be used for commercial purposes; this latter feature however, has shown considerable falling off during the past few months, due no doubt to the exorbitant prices asked and the enormous cost entailed for general manufacturing purposes. The production of munitions proceeds with unabated energy but the demands for equipment are not heavy. Other lines of activity are improving, especially shipbuilding and marine accessories, many plants for the manufacture of the latter having been recently established.

Pig Iron

The problem of how to supply the demand, is the outstanding feature of the iron and steel situation, and the runaway market continues, with quotations on the various grades climbing higher and higher. Activities throughout the States in connection with the war, have greatly increased the pressure upon the producing mills and smelters, with the result that prices on all commodities have been subjected to sharp and continual advances and it is reasonably expected that further advances will follow the increasing requirements for the United States Government. American pig iron in general, has again been advanced during the week. Canadian pig is virtually off the market and quotations are withdrawn.

Steel

The uncertainty of present industrial conditions seems to feature the general situation, but the assurance of a stronger and higher market appears to be a foregone conclusion, as the supply of raw and finished material is falling below the increasing requirements of the trade. A factor that may have considerable bearing upon the early future of the steel market is the fact that material such as, plates, shapes and bars, which had been reserved for the United

States Government at a price approximately 2.9c, has been allotted to the trade for other requirements, and it is anticipated that, owing to the rapid advance in pig iron during the past several months, additional contracts entered into by the American Government will be made on a much higher basis than that originally expected. The unprecedented upward movement in basic pig can only have one result, that is, a corresponding advance in semi-finished and finished materials. The ship building program, more especially across the line, is attaining such enormous proportions that the full capacity of present mills will be inadequate to meet the full requirements of the shipping interests, without the curtailment of commercial demands upon this particular grade of steel. Dealers here advise that during the past two months, the sales for strictly commercial purposes has gradually decreased, and it is further expected that outside of actual war requirements, the demands for the immediate future respecting private enterprise will be greatly reduced if not entirely disappear. Under existing conditions, with the cost of materials rapidly advancing, the expenditure for domestic purposes will be almost prohibitive, apart from the difficulty of securing the desired material. Pittsburgh prices on unfinished steel have again been advanced, this week's quotations showing a rise of $5 per ton. A sharp advance of about $25 per ton has been placed on forging billets and sales have been recorded as high as $135 per ton. Current quotations, f.o.b. Pittsburgh, are given in the selected market quotations. The market in plates is very strong owing to the heavy requirements for shipbuilding and car purposes, but some relief is expected within the next six months, as the production facilities are gradually being increased. The Pittsburgh price on black and blue annealed sheets has been advanced ½c per lb., the base quotation being approximately 8 cents per pound. Some relief has been given to the tin plate situation by the cutting off of supplies to the majority of these establishments manufacturing non-perishable goods, and reserving greater quantities for purposes where the use of tin plate is indispensable. Local dealers are looking forward to an early revision of sheet and tin plate prices. It is predicted that further advances in wire rods and wire products may be made within a short time, owing to the changing conditions of the market in raw materials. The sold up condition of the wrought iron and boiler tube mills maintains these markets in a very strong position, with the general tendency in an upward direction. The coke situation continues to be a factor in the production problem the quotation of $11 for spot furnace, and $12 for spot foundry is about $1 above that of the previous week.

Metals

The market generally has been quiet and inactive, and with the exception of lead might be said to have developed a weaker tendency. The situation is still influenced by the delayed action of the American Government, and uncertainty prevails. Copper is comparatively quiet with an easier tendency, Tin is inactive but firm, the trade awaiting the outcome of present permit negotiations. Dullness characterizes the spelter market and prices have declined. Lead is still the feature metal, the strength being reflected in another advance in price. Antimony has again weakened with a drop in price. Aluminum is firm and unchanged.

Copper.—There is no general change in the position of copper, and the American trade is awaiting the outcome of special conferences now being held by the large producers, regarding the price that should be paid by the government for future requirements. While the original understanding was that a years' supply would be arranged for at about 17c .there is a feeling that the quotation for additional copper should be closer to the present market, owing to the changed conditions and the fact that it costs small producers more to place metal on the market that the price first quoted. The London and New York markets continue firm with New York electro ¼c lower than last week. The local market is slightly easier with a one cent decline; lake and electro are quoted at 37½c, and castings at 36½c per lb.

Tin.—Interest is centered in the developments that are progressing between the Governments of the United States and Britain, to arrange for an adequate supply of tin for the future requirements of tin plate in the former country. The principal factor in this connection is the assurance that supplies of tin will not be hoarded for speculative purposes, but the requirements of the trade will be fully met, thus permitting the maximum production of essential tin supplies. A scarcity of spot metal has developed on the London market and prices for early positions have advanced but futures are easier. New York is a little stronger, an advance of one cent placing the spot price at 62c per lb. The local market is firm and unchanged at 62½c per lb.

Spelter.—The quiet market of the past week has developed into dullness and the situation has become somewhat easier, with prices on the decline. The demand is light and uncertainty prevails owing to the delayed action of the United States authorities. The New York market has declined ⅛c during the week, while local dealers report a very quiet situation and quotations are marked down 1½c, the price asked being 12c per lb.

Lead.—Heavy demand and short supply have again been the cause of a slight strengthening of the lead market. The leading producers have practically been out of the market for some time and resale metal is less in evidence. Independents are quoting the nominal price of 12¼c, this being an advance over last week of ¼c per lb. Dealers here continue to quote 14 c on a strong and steady market.

Antimony.—On declining demand and plenty of metal, the market has developed further weakness and prices have become easier. The quotation of 20c on the New York market shows a decline of one cent on the week. The local situation is quiet but firm with an easier undertone.

Machine Tools and Supplies

No new features have developed in the machine tool situation and the market continues to be one of steady activity but of a more normal character. The demands for shell making equipment have shown a falling off although some business continues to be placed for single machines or additional equipment to increase the present capacity. Inquiries for second hand tools, suitable for marine work, is occupying the attention of machine tool dealers, as many plants throughout the country are contemplating the manufacture of certain incidentals necessary for boat equipment. As the shipbuilding operations become further advanced, it is expected that activities in this direction will receive additional impetus. As would be expected under existing conditions, the cost of machine tool production is constantly advancing and in order to maintain a balance, the cost of equipment to the user is constantly becoming higher: this feature of the situation being likely to become more pronounced in the early future. The demand for all classes of supplies continues heavy, but prices are constantly advancing to meet the higher costs of raw materials and manufacture.

Scrap

While no apparent change has taken place in the general situation to warrant the sharp advance recently made on the New York market, the quotations would appear to indicate a much stronger market, but this may be partly accounted for by the heavy advances noted on the quotations of steel and iron, and the expectations of some large producers of scrap who desire to receive more for their supply than would be justified by actual conditions. However, the market is undoubtedly firmer, especially in iron and steel scraps, the average advance of the past week being about 3c or 4c per lb. The Pittsburgh price for sheet bar crops is now $48 per ton. Local price changes have been confined to boiler plate, machine cast iron and wrought iron pipe: the advances being 4c on the two former and 3c on the latter, the quotations being 15c, 24c and 17c respectively.

Toronto, Ont., June 19.—By the appointment of a fuel controller, it is hoped that the present unsatisfactory conditions in the coal trade will be eliminated. At present, prices are too high, and the shortage, although not acute, is very inconvenient, particularly to manufacturers. It is likely that the situation will have considerably improved by the fall. The recent orders for cars placed by the Dominion Government will do much to revive the car building industry as well as relieve the transportation situation. When financial conditions become more favorable there will be important orders placed for railroad equipment of all kinds, as both locomotives and cars are badly needed.

Steel

President Mark Workman's statement regarding the affairs of the Dominion Steel Corporation, reveals a very interesting state of affairs and shows that this concern is enjoying a wonderful period of prosperity. Incidentally it reflects the activity prevailing in the steel industry in Canada, which is an encouraging feature in that the steel trade is usually considered to be the barometer of trade generally. The corporation is booked up for fifteen months, and the unfilled tonnage is almost double that for the corresponding period of last year, all of which contains a non-cancellation clause. This concern's shell steel output for the first six months of 1918 has been disposed of. The expansion in the steel industry in Canada is further indicated by a statement recently issued from Ottawa covering the first quarter of this year. The production of steel ingots and castings reached a new high level at 152,-368 tons in March. The total production of 403,880 tons for the three months compares with 589,553 tons for the first six months of 1916.

High prices and backward deliveries continue to be the outstanding features in the steel trade. Although there is no indication when the upward movement in prices is likely to come to a stop, some authorities believe that this is not far distant. The situation, however, will not be affected to any great extent by the uncertainty as to what may develop as regards prices, as buying is for the most part of the hand-to-mouth order. Consumers now have to get steel when and where they can. Warehouse stocks are very low, and mill deliveries are very uncertain. Steel prices are largely nominal on account of the conditions prevailing, and fluctuations occur almost daily. Boiler tubes have taken another advance, being approximately 10 per cent. on seamless and 5 per cent. on lapwelded tubes. Current prices are, however, entirely nominal. Makers of both iron and steel tubes are sold up for a year or more ahead, but any mill that can spare tubes for reasonably prompt delivery can get any price it asks. Rivets have advanced; boiler rivets being now quoted at $7.10 and structural at $7 base. The demand for steel plates has been intensified by the American Government requirements for shipbuilding purposes. The market is very strong, and a further advance is expected before long. Prices of wrought pipe continue very firm, and an advance is likely in the near future. An advance in wire and wire products is expected soon.

The sheet market continues very strong and further advances are expected at an early date. The placing of tonnage for war requirements in the States is the principal activity in the market. On this account very few sheet makers are figuring in the market, and they are offering only limited quantities at high prices. Mill capacities have been mobilized to serve the Government which is taking surplus stocks ordinarily available for nearby shipments.

The sharp advance in prices of pig iron in the United States continues, and with no abatement of the excited conditions prevailing. Prices of all steel products are also advancing and the end is not in sight. The American Government and the Allies' requirements of steel will probably range from 25 to 40 per cent. of the country's output, according to estimates. The principal advances this week include billets, sheet bars, structural shapes, steel hoops and wire rods.

Pig Iron

The pig iron market is unsettled by the extraordinary high prices now prevailing, and consumers are now in search of suitable grades to substitute for those which have become exceptionally scarce or risen beyond the means of the buyer to purchase. The coke situation is also causing considerably anxiety on account of the shortage and extraordinarily high price . The steel mills as well as the furnaces are feeling the effects of the coke scarcity. Prices of domestic foundry iron are still withdrawn. Bessemer iron is now being quoted at $55.95 in Pittsburgh, while several other grades have reached the $50 mark.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the Commission headquarters are at Ottawa.

Scrap

The scrap market is dull and featureless, with prices at the same level as last week. Heavy melting steel is the only material that is at all active, and higher prices are expected. With this exception the demand for most scrap metals is light, consumers apparently not showing much interest in the market at the present time.

Machine Tools

There is nothing of much importance to note with regard to machine tools. The market is gradually assuming a more normal condition, and the demand is generally for machinery for general purposes. The high prices of machine tools are having a tendency to restrict business. Unless the requirements are urgent, consumers are inclined to wait until prices are more favorable. In the States the market is very active, there being an unusually heavy demand for large machine tools for shipbuilding and munitions purposes chiefly.

Supplies

The demand for a general line of machine shop supplies continues active at firm prices. Pure Manila rope has advanced 3½c, and is now quoted at 37c per pound. Differentials in certain classes of rope have been changed, which in some cases figures out as a slight net decline. Transmission rope and belt rope now carry a differential over base of 6c as compared with 8c formerly, which makes a net decline of ½c per pound. Drilling cables, however, have advanced ½c per pound by the changing of the differential over base size to 2c. White lead has advanced again, and is now quoted at $19 per 100 lbs., in ton lots. Turpentine has declined, and now ranges in price from 62½c to 69c per Imperial gallon. Linseed oil is also lower, ranging from $1.43 to $1.46 for boiled oil; raw oil being 3c cheaper.

Metals

The metal markets continue firm, due principally to expectation of a large volume of business rather than to any great activity at the present time. The requirements of the American Government are not yet known, and there is still a feeling of uncertainty in the market as to what may develop. The local situation is unchanged, and the outlook generally continues favorable. Prices are firm and unchanged on the basis of last week's quotations.

Copper.—The market is quiet, but firmer, notwithstanding the comparatively small volume of business. Most of the leading producers are now out of the market for delivery before September. More interest, however, centres on later positions, and fourth quarter copper shows greater proportionate strength than the nearer positions. Prices continue nominal, lake and electrolytic being quoted at 38c and castings 37c per pound.

Tin.—The tin situation is unchanged and the market continues firm. A feeling exists in the trade that permits for shipping tin from England will in the near future be easier to obtain, which will tend to weaken prices. Tin is firm locally and quoted at 66c per pound.

Spelter.—The market is dull and demand light, although prices are holding firm at 12c per pound.

Lead.—The market is slightly easier, but quotations are unchanged. Producers continue to keep out, and are offering no new lead for sale. Increased production during the rest of this month, and in July is expected, and in this event there may be more lead for sale, which will naturally tend towards an easier market and lower prices. Local quotation unchanged at 11¾c per pound.

Antimony.—The demand is light and the lack of buying interest has had its effect in an easier market, especially for prompt delivery. Demand is principally confined to the more distant positions, which are proportionately firmer than the nearby. Local price 26c per pound.

Aluminum.—There is no change in the situation. The supply is still light and prices firm at 68c per pound.

Sydney, June 15.—Meetings have been held during the week beginning June 11 between the representatives of the Provincial Workmen's Association and the United Mine Workers of Nova Scotia. It is stated that a basis of amalgamation is likely to be reached, and that a fusion of the two labor unions may be expected shortly.

The Acadia Coal Co. has granted an increase to the day laborers employed at its collieries. All day rates under $2.65 are increased 15 cents per day, plus an increase varying between 6 per cent. and 9 per cent., applied in addition to the 6 per cent. increase given in December last. day laborers rated at above $2.65 per day and miners are granted an increase of 9 per cent., also applicable in addition to the 6 per cent. previously given. This latest adjustment brings the minimum wage of the common laborer to $2.37 per day.

Sydney has had a visit from Arthur A. Colê, the president of the Canadian Mining Institute, who is acting as field officer of the Advisory Council at Ottawa, who are undertaking an inventory which it is hoped will lead to a "mobilization" of the industrial and research facilities of the Dominion. Mr. Cole also conferred with the executive of the Nova Scotia Mining Society regarding the mooted affiliation of this society with the Canadian Mining Institute.

Coal Production

Coal production is being fairly well maintained, although some slight decline is noticeable with the finer weather. Farming operations and potato planting are in advance of any previous year in the life of the mining districts. The Dominion Coal Co. itself has planted sufficient land with potatoes to yield, under ordinary weather conditions, between 6,000 to 8,000 bushels. This is in addition to the individual plots of the miners, who are being assisted by the company in every possible way. The same may be said of the Sydney district and the steel employees.

The construction of two new blocks of coke ovens for the Dominion Iron & Steel Co. at Sydney is now well in progress, and a large number of men are employed on the work.

It is said that the areas of the Mabou & Gulf Coal Co., in Inverness County, with the equipment and railway, is likely to be acquired by a strong American concern, and that active mining operations may be resumed. The property has been idle ten or twelve years, following the flooding of a development slope.

The Scottish Hero, one of the Dominion Steel Corporation boats engaged in Transatlantic trade, has been torpedoed. This is the third vessel lost in this service. The Morwenna was torpedoed last year, and the Sheba was lost, but whether she was destroyed by mine or torpedo, or otherwise, is not known. The Storstad was torpedoed earlier in the year. This vessel was under charter to the Steel Co., and was sunk while acting as a Belgian relief ship. The captain of the Scottish Hero was also captain of the Morwenna when she was sunk. The fate of the crew of the Hero is not yet known.

Pittsburgh, Pa., June 16.—Business in the steel market has come almost to a standstill, as the large Government requirements hang over the situation, but are not expressed in actual orders, so that producers do not know where they stand, and consumers realize that placing orders with the mills would not do any good, as the latter are in no position to give any inkling as to when they would be able to ship. Steel manufacturers returning from Washington say that matters are in apparent chaos there, plans being worked upon, but not reaching the stage at which definite orders can be given. Possibly the fact that the war budget bill of $3,340,000,000 has been passed, and was signed by the President on June 15, will release some orders, but it is somewhat doubtful whether important orders have been held up on that account.

There is no basis on which anything like a close forecast can be made as to the amount of steel the Government will eventually require for its own use or for its Allies, but it is distinctly possible that the total may reach 40 or 50 per cent. of the country's output. It is true that the purchases for account of the Entente Allies will in considerable measure be a replacement or a continuance of the orders they have hitherto been placing, but when they reduced their buying some months ago the trade was assumed to be gone, and the mills have been filling up with other orders, so that the fresh buying will have the aspect of new business.

Indications are that the programme for building steel freighters by the Emergency Fleet Corporation, General Goethals, general manager, are working out even better than expected, and that it will be possible to provide a very large shipyard capacity for consuming steel in that manner. Eventually this shipbuilding will probably consume at least 3 per cent., and perhaps up to 5 per cent., of the total steel output, this being apart from steel used in building war craft. Then there is the plan, reported a week ago, for the Government to buy 100,000 freight cars. Probably all these cars, if secured, would be used on American roads, being leased for the duration of the war, and then sold to the roads at a suitable price. Purchases for Russia and France would probably be in addition. No announcement as to locomotives has been made, except that there is a committee on locomotives similar to that on cars. The cars and locomotives together might take 5 per cent. or more of the steel production. How this would disarrange regular commercial operations is shown by the fact that car shops have lately been refusing to quote at all on inquiries from South America, stating that they cannot possibly secure any steel from the mills for such a purpose. In case the Government ordered the cars, the steel mills would simply be asked to furnish the steel, to the delay of other orders.

All the mills and their customers can do is to wait until the Government plans are brought to a head, and it is seen how much steel can be used. It is not a case of finding steel so much as it is a case of finding shop or shipyard capacity to work it up into the desired forms. Necessarily the mills as a rule simply take the attitude that they are out of the market, except for Government requirements. Some contract business is being placed, of course, but it is simply of routine character, the mills booking additional tonnages from regular customers, to be shipped whenever present contracts are worked out.

Steel

There are no defined market prices for finished steel products. There is no longer a regular market "for shipment at mill convenience," and prices for early deliveries, say, in three to six months, vary according to circumstances. These prices still show an advancing tendency. Black and blue annealed sheets are, say, half a cent. a pound higher, at 7.50c to 8.00c, while merchant bars are up about a ¼c, to, say, 4.25c to 4.50c. Orders can hardly be placed at all except by regular customers. Shapes are still nominally 4.25c to 4.50c.

Exports

Iron and steel exports in April amounted to 521,176 gross tons, against 606,563 tons in March, 449,107 tons in February, 608,286 tons in January, and a monthly average of 509,000 in 1916. It is recalled that last March there was a large tonnage of steel at seaboard awaiting vessels, and it is quite likely that of late the actual shipments from mills and furnaces have been at a considerably smaller rate than would be suggested by the statistics of actual exports.

Pig Iron and Scrap Rise

Furnaces continue to mark up pig iron prices, there having been an average advance of about $2 a ton in the past week. Prices are now squarely on the basis of $55 for Bessemer and $50 for basic, malleable and foundry, at valley furnaces, with $53 paid on some small lots of foundry and malleable for early shipment. The furnaces are indifferent about selling, as they have disposed of a fair fraction of their output for the first half of next year, and have little left for this year. Their attitude is a natural one, seeing that up to date they have not, on the whole, profited one cent by the advance. The majority of them are still shipping $18 iron, sold last August, and as they have had to pay fancy prices for spot coke to eke out their insufficient contract deliveries, they frequently show a loss on the month's business.

For about a week the Carnegie Steel Company paid $40 for all the heavy melting steel offered, raising its bid in the past few days to $42, while dealers are now talking $45 or even higher.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

ENGINEERING

Hamilton, Ont. — The National Machinery Co., will build a plant here.

Ottawa, Ont.—The Ottawa Car Co., has let contracts for the erection of a repair shop to cost $60,000.

Vancouver, B.C.—The Western Iron Works will build a boiler shop to cost about $30,000. Hodgson & King have the contract.

Three Rivers, Que.—The Three Rivers Casting Co., will build a brick foundry at a cost of $35,000 and will be in the market for foundry equipment, lathes, etc.

Montreal, Que.—N. M. Loney,, engineer, of the American Can Co., Maisonneuve, is asking for prices on two 150 h.p., 150 lb. pressure return tube boilers. Head office 120 Broadway, New York.

Chatham, Ont.—The Gray-Dort Motor Co. have purchased the plant formerly owned by the Blonde Lumber Co. They will utilize the plant for the manufacture of auto bodies.

Fort William, Ont.—It is considered likely that the Canadian Car & Foundry Co. will build a large number of cars here in connection with the order which they recently received.

Port Arthur, Ont.—The foundations for the Port Arthur Pulp & Paper Co.'s mill are practically completed and construction well under way. Most of the contracts have been let.

Prince Rupert, B.C.—An effort is being made by the City Council and Board of Trade to find some means of utilizing the drydocks and shipbuilding plant which has been practically idle since its completion about 12 months ago.

Sarnia, Ont.—With a view to branching out more extensively into brass manufacturing after the war, when the munitions business will be abandoned, the Mueller Company is laying plans for adding an extension to its present plant for the manufacture of brass rods, tubes, etc.

St. John, N.B.—A meeting of the hospital committee from the municipal council was held on June 11 at the General Public Hospital. Dr. Thomas Walker presiding, to open tenders for the work of installing boilers and other equipment in the new power house. Considerable attention was given the matter, but no decision was reached.

Haileybury, Ont.—An effort is to be made to induce the Riordon Pulp and Paper Co. to erect the large plant which has been under consideration for some time, at this place. Mayor Wright visited Montreal recently and interviewed the president of the Riordon Company in regard to the selection of Haileybury as the most suitable site in the North Country for their plant.

Edmonton, Alta. — The Edmonton Cement Co., has been reorganized and the plant at Marlboro on the G.T.R. will be put in operation by August. The capacity of the mill will be increased to 2250 barrels of cement per day. Alexander Macdonald of Winnipeg is the new president and John A. MacDougall of Edmonton is managing director.

Halifax, N.S.—A branch factory is to be established at Halifax by the L'Air Liquid Society, the Canadian headquarters of which are at Montreal, where the company has a large factory. Negotiations for the purchase of a lot have been completed by Charles Royer, the general manager, who is in Halifax this week. The factory will be located in the vicinity of the Cotton Factory siding, and will be 100 x 50. The company will manufacture accetylene cutting and welding machines.

GENERAL

Hamilton, Ont.—The National Paper Goods Co., will build an addition to its factory to cost $10,000.

Drummondville, Que.—It is understood that the Aetna Explosives Co., will shortly close down their plant here.

Dennison Road, B.C.—The Fir Tree Lumber Co., Fraser Valley, Dennison Road, B.C., will build an electrically operated sawmill to cost $60,000.

Winnipeg, Man.—The Stewart Sheaf Loader Co., manufacturer of agricultural implements, etc., will build a new factory. J. S. Menzies is manager.

Toronto, Ont.—The Cowan Co., 72 Sterling road, has been granted a permit to erect a one-storey brick addition to their cocoa factory at a cost of $3,000.

Regina, Sask.—On June 11, the Regina Storage and Forwarding Co.'s plant was destroyed by fire with virtually all the contents. The building and cold storage plant, valued at $27,000, is a total loss. It was partly covered by insurance. The contents were valued in the neighborhood of $150,000; insurance being held by individual owners. Defective wiring is believed to have been the cause.

MUNICIPAL

Iroquois Falls, Ont.—The Abitibi Power & Paper Co. will build a new steel tower transmission line for high voltage transmission.

Cobalt, Ont.—The Town Council have definitely decided to instal a telephone system as soon as the franchise of the Timiskaming Telephone Co. expires.

Montreal, Que.—A. Pion the contractor announced recently that he had made satisfactory arrangements enabling him to undertake the construction of the La Salle bridge over the aqueduct.

St. Mary's, Ont.—A by-law will be submitted to the ratepayers on the question of a sliding scale bonus of $5,000 to the Thames Quarry Co. If the company uses sufficient electrical energy in one year to give a $1,000 profit to the town, one-fifth of the profit is to be returned to the company until the $5,000 is paid out.

Wellington, Ont.—A series of meetings are being held here, called by Reeve Clarke, relative to supplying this village with hydro power in the event of its being introduced shortly into Prince Edward County. It is suggested that the village take 75 horse-power at a given rate from the commission and sell the power to consumers.

Toronto, Ont.—According to Works Commissioner Harris the new Bloor street viaduct will not be opened for traffic until the middle of next summer. The Commissioner has informed the Board of Works that while the structural work may be completed before the end of the year, it would be inadvisable to lay a pavement on the bridge during the cold weather, Commissioner Harris said that he did not intend to lay the pavement until the structural work was completed.

Winnipeg, Man.—An inventory of the machinery and scrap metal that the city owns is being made with the object of selling it. Lists that have so far reached the Board of Control from department heads, indicate that a vast amount of material has accumulated during recent years. There are numerous engines, power street rollers, constructional equipment, dismantled bridges, and tons of scrap metals. It is expected that a considerable part of the machinery can be sold to western towns or to contractors. The total value is estimated at $50,000.

TENDERS

Pointe Claire, Que.—Tenders will be received by J. B. Martin, secretary-treasurer, up to June 27, for water filtration plant and low lift pumps. Plans and specifications may be obtained from R. S. and W. S. Lea, 809 New Birks Bldg., Montreal.

Toronto, Ont.—Tenders are now being received by the owners and sub-tenders by the Sherwood Construction Co., Mail Building, for the erection of a $125,000 reinforced concrete packing plant for the Swift Canadian Co., West Toronto.

Toronto, Ont.—Tenders, addressed to the secretary-treasurer of the Board of Education, will be received until June 28, for electrical work, etc., required for manual training and domestic science centres in Earl Grey Public School, Jones Avenue, also midsummer repairs—sundry trades. Specifications may be seen and all information obtained at the office of the superintendent of buildings, Administration Building, 155 College Street.

Kingston, Ont.—Tenders will be received until July 16, for the reconstruction of part of the cribwork wharves at the entrance to the Dry Dock, at Kingston, Ont. Plans and forms of contract can be seen and specification and forms of tender obtained at the Department of Public Works, Ottawa, the offices of the District Engineer, Equity Building, Toronto, Ont., and on application to the Postmaster, at Kingston, Ont.

Montreal, Que.—Tenders for the supply and installation of underground cables, street pedestals, fire alarm boxes, cable boxes and accessories for St. Lawrence Boulevard from Craig to Sherbrooke and intersecting streets, addressed to the Board of Commissioners, will be received until June 26. The specification, forms of tender and all required information may be obtained at the office of the Superintendent of Purchases and Sales, City Hall.

CONTRACTS

St. Lambert, Que.—The Town Council has awarded the contract for a centrifugal pump to Laurie & Lamb of Montreal.

Welland, Ont.—The Electro-Metals Co. have placed an order with the Storey Pump & Equipment Co., for one 8-inch "Morris" turbine pump having a daily capacity of two million gallons.

Ottawa, Ont.—A contract has been awarded by the Dominion Government to the Canadian Car & Foundry Co. for 3,000 freight cars for the Government Railway System.

Iroquois Falls, Ont.—The Abitibi Power & Paper Co. have awarded a contract to the Bawden Pump Co., Toronto, for four centrifugal pumps, each of one million gallons daily capacity.

Port Arthur, Ont.—The Port Arthur Pulp & Paper Co. have awarded a contract to the Storey Pump & Equipment Co., Toronto, for two 10 x 6 x 12-inch "Deane" duplex, end packed plunger boiler feed pumps.

BUILDING

Hamilton, Ont.—A permit has been issued to the Bell Telephone Co., for a new exchange building to be erected on Garfield avenue, at a cost of $46,000.

Toronto, Ont.—The Canadian Dyers' Association, Liberty Street, has been granted a permit to add a one-storey brick structure to the factory at a cost of $8,000.

TRADE GOSSIP

Montreal, Que.—The C.P.R. has 2,000 cars under construction at the present time. They will be distributed to all parts of the system. In addition, twenty-five new Decapod locomotives are being built for use on the mountain division.

The Bawden Pump Co., Toronto, have been awarded a contract by Fraser's, Ltd., Edmunston, N.B., for 14 centrifugal pumps of from one to four million Imperial gallons daily capacity, and also a compound boiler feed pump. This equipment is for a new pulp and paper mill.

The Storey Pump & Equipment Co., Toronto, have recently been awarded the following contracts: Two 4 in. double suction Morris centrifugal pumps for the Swift Canadian Co., Toronto; two 4-stage Morris turbine pumps for Gravenhurst, Ont.; one 4 in., 4-stage Morris turbine pump for the Canadian Copper Co., Sudbury, Ont.

Loans $10,000,000 to Munitions Board.—The C.P.R. has made a loan of $10,000,000 to the Imperial Munitions Board, so the company stated recently. The last balance sheet of the C.P.R. of the date of December 31, 1916, showed $57,076,018 in cash on hand, and it is from this the company is able to make the loan.

Newfoundland Pulp May Go to the U. S.—The Newfoundland Legislature, now in session, is expected to enact a law permitting export to the United States of a considerable quantity of pulpwood, cut in the colony since the outbreak of the war. The wood was intended for shipment to England and France, but because of the shortage of ships its transfer to those countries has become impossible.

Shipments of Pulp.—The increased facilities for shipping brought about through the opening of the St. Lawrence have had a beneficial effect on many Canadian industries. Recently the Riordon Pulp and Paper Company have sent a shipload of sulphite pulp to Spain, while another is to be shipped shortly to Calcutta. A quantity of pulp has been sent to Italy, but the risks attendant thereon are so great as to make trading in that direction undesirable.

Vancouver, B.C.—The Rainy River Pulp and Paper Co., whose mill is at Port Mellon, Howe Sound, has commenced the production of kraft pulp. The plant has been changed from a soda paper mill to a kraft pulp and paper plant, and that accomplished in record time. The plant was purchased by the Rainy River Pulp and Paper Co. from the previous owners on February 1, 1917. The plant is thoroughly organized and equipped for the production of kraft pulp as well as the finished paper, for which there is an unlimited demand.

Safety Equipment On Railway Cars.—An extension of time for the equipping of their cars with certain safety devices regarded as necessary for the safety of railway employes, and ordered by the Dominion Railway Board in July of 1914 has been secured by the C.P.R. and G.T.R., when their representatives appeared before the Board, and pointed out that owing to the lack of labor it has been impossible for them to equip their cars according to schedule. The period of extension will not be fixed until the return of Chief Commissioner Drayton from the West.

Start Shipping Rails to France.—Rails for the battlefront in France and Flanders are being procured from the line of the Grand Trunk Pacific through the Yellowhead Pass from Imrie to Resplendent, a distance of 207 miles. By the use of rails from the Canadian Northern line between the two points a composite line will be laid which will serve the industries of the district and put the settlers to the minimum amount of inconvenience. The composite line will be constructed on 128 miles of C.N.R. roadbed and 77 miles of G.T.P. The first shipment of rails will be in transit to Three Rivers this week and the balance will be on the way by the end of July.

Plan New Metal Committee.—The Department of Commerce, Washington, D. C., has authorized the following statement: As a result of a meeting attended by the representatives of the tin industry, held at the office of the Bureau of Foreign and Domestic Commerce, the American Iron and Steel Institute will be asked to call a meeting to form some sort of an organization to be responsible to the bureau for the equitable allotment of pig tin in this country. It is understood by the bureau that the British Government has signified a willingness to turn over this important duty to the Department of Commerce of the United States.

Manufacturers Miss Opportunities in France.—Philippe Roy, the Canadian Commissioner-General at Paris, says that the reason why Canadian manufacturers have not been able in the past to do business more extensively in France is that they have been unable to quote prices on goods delivered at French ports. The French business man, he says, wants to pay for what he buys in France and in francs. Consequently the question of transportation and exchange must be solved by the exporter. It has been because the Hudson Bay Company was able to give satisfaction to the French Government on these two points that it has been enabled to place important orders in Canada.

Abundant Coal Promised West.—The important announcement was made on June 13 by Dr. Ruttan, of the Government's Research Council, to the Manufacturers' Association at Winnipeg, that Western Canada will have abundance of coal within a very short time at a price about two-thirds the price of anthracite. This will be secured by a process for the treatment of lignite coal lying in such vast quantities in Western Canada, and, according to figures given by Dr. Ruttan, there can be turned out from Winnipeg from 100,000 to 200,000 tons daily. The whole scheme for this undertaking is complete, and has been recommended to the Government, the preliminary cost of equipment being given at $400,000.

Cars Ordered for Government Roads.—Contracts for the construction of 5,000 cars for the Canadian Government Railway System have been let by the Government and orders for another 2,000 will be placed in the near future. Contracts were made some weeks ago with the Eastern Car Co. and the Canadian Car & Foundry Co., under which each concern is to build 1,000 cars. Last Thursday a second contract for 3,000 additional cars was awarded the Canadian Car & Foundry Co. At the same time 50 loco-

Canadian Agents:—WILLIAMS & WILSON, LTD., MONTREAL; THE A. R. WILLIAMS MACHINERY CO., LTD., TORONTO, WINNIPEG AND ST. JOHN, N.B.

motives for the Government Railway System are being constructed at Kingston, and a like number in Montreal. The Intercolonial and Transcontinental will thus, when the orders are all completed, have 7,000 more cars and 100 more locomotives to meet traffic requirements.

High Water Level for Lake of Woods.—Measures for maintaining the Lake of the Woods with a level which will, in their opinion, secure to the inhabitants of both sides of the international boundary the most advantageous use of the waters of that lake, flowing into and out of the lake, and of their shores and harbors, are recommended in a report of the International Joint Commission which has been made public simultaneously at Ottawa and Washington. The six members of the commission have recognized water power as the dominant interest of the region, and have provided for the utilization of the Lake of the Woods and the upper lakes as immense storage reservoirs for the benefit of that interest. They have considered the interests of navigation, the fisheries, agriculture, lumbering, manufacturing, mining, and tourist travel, and have recommended that the Lake of the Woods be maintained at 1061.25 sea level datum.

Canadian Electric Railway Association.—At the recent annual meeting of the Association held in the Windsor Hotel, Montreal, the following officers were elected for the ensuing year:—President, C. L. Wilson, assistant general manager, Toronto and York Radial Railway, Toronto; Hon. Sec-Treas., Acton Burrows, Toronto. The Executive Committee is as follows: J. D. Fraser, director and secretary-treasurer of the Ottawa Electric Railway, Ottawa; A. Gaboury, superintendent Montreal Tramways, Montreal; E. P. Coleman, Hamilton; G. Gordon Gale, vice-president and manager, Hull Electric Railway, Hull; J. S. Mackenzie, purchasing agent, Winnipeg Electric Railway, Winnipeg; H. G. Matthews, general manager, Quebec Railway, Light, Heat & Power Co., Quebec; E. L. Milliken, manager Cape Breton Electric Railway, Sydney, C.B., and Aubrey A. Burrows, Toronto.

Canadian Trade Bounties.—According to the latest report of the Department of Trade and Commerce at Ottawa, trade bounties amounting to $21,669,965 are paid out annually. The following amounts were paid out in one year, according to the Government's statistician:

	Amount, Tons.	Bounty, Dollars.
Pig Iron	5,431,547	7,097,041
Puddled Iron Bars	42,812	113,674
Steel	4,448,780	6,706,990
Manufactures of Steel	499,312	2,868,122
Lead (pounds)	1,187,083,350	1,979,164
Manila Fibre (pounds)	108,048,641	367,962
Crude Petroleum (gals.)	169,134,123	2,537,012
Total bounties		$21,669,965

INCORPORATIONS

The United Brush Co. of Canada, Ltd., has been incorporated at Ottawa with a capital of $50,000 to manufacture of brushes of all kinds at Hamilton, Ont. The incorporators are Morris Fletcher, Harry Nex and Alex. W. Brown all of Hamilton.

Holden-Morgan Thread Miller, Ltd., have been incorporated at Toronto with a capital of $600,000 to carry on the business of mechanical engineers and manufacturers at Toronto. The provisional directors are W. A. Y. Case, J. B. Taylor and W. M. Smith all of Toronto.

The Pressed Metals Co., of Canada, Ltd., has been incorporated at Ottawa, with a capital of $2,000,000 to manufacture and deal in iron, steel, brass and all other metals. The head office is at Toronto and the incorporators are Charles E. Calvert, H. L. Nussbaum and W. T. Fraser all of Toronto.

The Canada Iron Products Co., have been incorporated at Ottawa with a capital of $1,000,000 to manufacture and deal in iron, steel, coke, colors, paints and chemical preparations of every description. The head office is at Montreal and the incorporators are R. E. Allan, J. P. Charbonneau and William Taylor all of Montreal.

RAILWAYS—BRIDGES

Ridgetown, Ont.—The M.C.R. contemplate erecting a water tank here.

Edmonton, Alta.—In the Lacombe district great interest is being taken in the building of the Lacombe & Blindman Valley electric railway, which is now being gradually pushed forward to completion. Steel for the line as far as the outlet has already been bought and several carloads of rails and angle bars have already arrived at Lacombe, and every few days more carloads are being shipped in. The laying of the rails has now begun.

REFRIGERATION

Windsor, Ont.—D. D. Drulard has had his meat market equipped with a 3-ton refrigerating plant, supplied by the Frick Co., Waynesboro, Pa.

Montreal, Que.—The International Manufacturing Co. has installed a 120-ton refrigerating plant, supplied by the Frick Co., Waynesboro, Pa., for cooling purposes in their munitions factory.

St. Johns, N.F.—The Reid Newfoundland Co. is erecting a cold storage and fish freezing plant near the railway station. the main building to be of concrete 200 x 99 feet, three storeys high. The cold stores are to have capacity for about 10,000,000 pounds of fish. It is planned, in addition, to build six branch plants at export stations, the first of these to be erected at Port-aux-Basques, which is to have cold storage capacity for 2,000,000 pounds of fish. The other branch houses, it is stated, will be probably at Bonavista, Lewisport, Bay-de-Verde, Placentia and Trespassey, and will be of about 500,000 pounds capacity each.

PERSONAL

W. P. Hinton, traffic manager of the G.T.R., will, it is understood, be appointed general manager.

George Beardmore, Toronto, and **W. G. Ross**, of Montreal, president of Asbestos Corporation of Canada, have been elected to the board of directors of the Canadian General Electric Co.

S. R. Parsons president of the British-American Oil Co., Toronto, was elected president of the Canadian Manufacturers Association at the annual meeting in Winnipeg last week.

John Wilson, of the engineering staff of the Structural Steel Co., Montreal, has joined the contracting-engineers' staff of the Dominion Bridge Co., at Lachine, P.Q.

T. A. Russell of the Russell Motor Co. and **Holt Gurney** of the Gurney Stove Co., Toronto, have been appointed by the Imperial Munitions Board to purchase machinery for the wooden vessels under construction in Canada.

Edward Holgate, who has been chief draftsman with the Structural Steel Co. of Montreal for the past seven years, has accepted a position as chief engineer with MacKinnon, Holmes & Co., Ltd., of Sherbrooke, Que.

Reginald H. Balfour, has been appointed sales manager of the Eugene F. Phillips Electrical Works, Ltd., Montreal. Mr. Balfour is a graduate of McGill University. He was formerly engineer for the Montreal Electrical Commission.

H. W. Hutchinson, of Winnipeg, vice-president of the John Dere Plow Co., director of the Dominion Bank, and closely identified with many other large institutions, has been elected to the directorate of the Sawyer-Massey Co., of Hamilton, Ont.

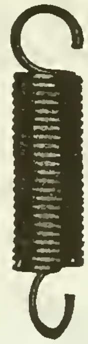
R. J. Younge, general manager of the Export Association of Canada, Montreal, who went to South Africa last March in the interests of the association and its trade relations with that country, is now at Johannesburg. He plans to sail on his return to Canada on July 6.

C. B. Gordon, president of the Dominion Textile Co. of Montreal, and a member of the Imperial Munitions Board in Canada since it was organized, will, it is understood, become purchasing agent of the British Government in the United States, so far as munitions are concerned. Mr. Gordon is at present in England.

Henry Hague Vaughan, who was recently appointed to a high executive position with the Dominion Bridge Co., has now been made general manager of the company. **Mr. Duggan**, the former general manager, becomes chairman of the Board of Directors, and also retains the title of chief engineer of the company.

John William Seens, general manger of the Structural Steel Co., Montreal, has joined the engineering staff of the Canadian Bridge Co., of Walkerville, Ont,. the plant of the Structural Steel Co. having been taken over by the Montreal Locomotive Works.

W. Sanford Evans, chairman of the Georgian Bay Canal Commission, has ben requested to accept the position of



ON PAGE 70
You'll find a host of Opportunities.
TURN TO IT!

food controller for Canada during the war. The Order-in-Council defining the duties and powers of controller has been submitted to Mr. Evans, who will make any recommendations he considers necessary to ensure success to this proposal to regulate prices and distribution of food supplies.

D. W. Fraser, who for a number of years has been works manager of the Montreal Locomotive Works, has been promoted to the position of general manager and will have charge of the city office as well as that af the plant. His present activities will be divided between the plant and the head office, but with the passing of Government work and a return to the construction of locomotives, Mr. Fraser will be permanently located at the city office.

James Walter Lyon, president of the Guelph Radial Railway, is also president of the Guelph Junction Railway, vice-president of the Dominion Linen Mills, Ltd., director of Preston Car and Coach Co., director of Sterling Rubber Co., and president of the Guelph Realty Co. Mr. Lyon was born in the United States and came to Canada in 1872. He is president of the Hydro Radial Association of Canada, which plans a system of railway lines throughout Ontario.

R. H. Parks has been appointed operating manager of the Canadian Car & Foundry Co., Montreal. Mr. Parks who will have charge of the operation of all the car plants has been identified with the car building industry for a great many years, and came to Canada from the Bettendorf Car Co. of Davenport, Ia. Coincident with this appointment, **W. S. Atwood** has been appointed assistant to the vice-president and managing director.

Donald Grant, builder of many railroads in the northwest, died at his home on June 13, at Faribault, Min., after a short illness. Mr. Grant was born in Glengarry, Canada, December 10, 1837. He went to Minnesota in 1863, entering into the railroad construction work. He assisted in building sections of the Chicago, Milwaukee and St. Paul, the Northern Pacific, the Great Northern, the Minneapolis and St. Louis, the Canadian Pacific and many smaller lines in the northwest.

Charles A. Magrath, who has been appointed fuel controller for Canada, is chairman of the International Joint Commission on Waterways. Mr. Magrath was born in North Augusta, Ont., fifty-seven years ago. In 1878 he went to the Canadian West and engaged in irrigation and other development work in Southern Alberta. Later he received an appointment as a member of the International Joint Commission, on which he has done excellent work. He was chairman of the temporary Commission erected in 1913 by Ontario to investigate and report on a comprehensive system of highways for that province. He will have complete power over the fuel supplies of the Dominion, their distribution and prices at the various points throughout the country. The purpose of the appointment is to insure for the people a domestic supply during the coming winter.

Lawford Grant has been appointed manager director and treasurer of the Eugene F. Phillips Electrical Works, Ltd., Montreal. Mr. Grant came to Canada in 1907 as president and managing director of the Canadian British Insulated Co., Ltd. In 1913 he accepted a position as assistant manager of the Phillips Co., and now succeeds Geo. H. Olney, who was head of that firm for eighteen years, Mr. Olney having recently retired owing to ill-health. Mr. Grant is a civil and electrical engineer, and was formerly engineer for the British Insulated and Helsby Cables, Ltd., of England. Among the many undertakings which he carried out for the latter company was the electrification of the Government dock yard and naval base at Malta. The Phillips plant is, in size, among the first half-dozen of the insulated wire and cable works on this continent.

MARINE

Vancouver, B.C.—The Foundation Co. has been awarded contracts to build five wooden steamships for the British Government through the Imperial Munitions Board. The ground has been broken on the Songhees Reserve site, and work will be rushed to get the plant ready.

North Vancouver, B.C.—It is reported here that a deal has been completed for disposal of a portion of the Wallace shipyard interests. No authoritative statement regarding the matter is obtainable but it is reported on good authority that the western Wallace yard, that used in connection with the construction of wooden ships, is to be transferred to the Foundation Co., of Montreal.

Victoria, B.C.—The shipbuilding plant operated by the Cameron Genoa Mills Shipbuilders, Ltd., where the auxiliary schooners are now in various stages of construction, is to be enlarged for the purpose of making an immediate start on the four wooden steamers which have been awarded the concern by the Imperial Munitions Board. A new building ways is being laid down on the ground now under lease to the company.

Pier and Warehouse Collapse.—A section 150 feet long of the city pier No. 5 at West St. John collapsed at noon on June 13, with an equal stretch of warehouse and part of a grain conveyer. Three men had been in the warehouse office, but left only ten minutes before the collapse occurred. Forty men had been working in the warehouse. Too much weighty goods in the warehouse is given as the cause. Some six thousand cases of heavy goods for export were lost.

Vancouver, B.C.—Within the next three months it is expected that the first keel of the six new vessels that are to be built in Vancouver for the Imperial Munitions Board will be laid by the new concern known as the Western Canada Shipyards, Ltd. The amalgamation of three well-known companies has resulted in the formation of this concern, these companies being Grant, Smith & McDonnell, the Northern Construction Co., and Armstrong & Morrison. Operations have already commenced for the laying out of the site of the shipyard, on the location of the old Royal City Mills on the north side of False Creek, a lengthy lease having been obtained by the board on behalf of the company. Thus the initial measures have been taken that may mean the establishment on a permanent basis of one of the largest shipbuilding plants in the Dominion. A. R. Mann, of the Northern Construction Co., is president and managing director of the concern.

Vancouver, B.C.—R. P. Butchart and Capt. Troup representing the Imperial Munitions Board have given assurance that all the auxiliary machinery for the vessels will be built and procured here. This includes hoisting equipment and gear, and all of the hundred and one items of metal outfitting other than the engines themselves. The detailed plans for the engines are not all available so far and final decision regarding them will not be made until some further information has been received. from Ottawa. But it was represented that from twelve to fifteen engines can be built in the present British Columbia shops, including those in Vancouver, North Vancouver, Victoria, New Westminster and Prince Rupert.

CATALOGUES

Stow Grinders.—The Stow Mfg. Co., Binghampton, N.Y., have issued a bulletin featuring their line of internal grinders and flexible shaft equipments for munitions. The bulletin also illustrates Stow portable tools for various purposes.

Service Bureau Bulletin, issued by the National Founders' Association, Chicago, Ill. Bulletin No. 6 deals with various types of hand squeezers, with pattern and flask equipment, etc., particularly as to the attainment of satisfactory results and saving of time. The bulletin is fully illustrated.

Lathes.—Loose-leaf binder, containing a number of leaflets dealing with an interesting line of lathes manufactured by the Whitcomb-Blaisdell Machine Tool Co., Worcester, Mass. The various sizes of lathes are illustrated, together with a specification and principal dimensions covering each. The concluding pages of the catalogue deal with the reversible geared head lathes, with illustrations and specifications.

Planers.—The Whitcomb-Blaisdell Machine Tool Co., Worcester, Mass., have issued a catalogue illustrating and describing a line of planers which they manufacture. The catalogue contains a general description of the Whitcomb-Blaisdell second-belt drive planers, and deals with the advantages derived by the use of this type of drive. The principal features embodied in the design of these planers are illustrated and described at length, while the various sizes are also illustrated and accompanied by a specification giving the principal dimensions. This is a very attractive catalogue, and the illustrations are unusually good.

Advertising as the Quick Rescuer in England's Crises

What It Has Done and How the Government Proved Its War Time Use.

By J. Murray Allison

Formerly Advertising Manager of the London Times, late Assistant Director of Recruiting, Royal Naval Division

MANY of the men who have enjoyed your overflowing hospitality in happier days gone by are in the trenches, the dust of many lies quiet in France, others in khaki or navy blue guard those little islands in the North Sea, many, also in uniform, are in the War Office, the Admiralty or in the Ministry of Munitions, while the rest, in the plain clothes of the civilian, still carry on their craft, a craft now devoted to the common object of us all, the winning of the war.

For, let there be no mistake, advertising plays a very important part, indeed, when war becomes, as this war has become, not merely the clash of armed forces, one against the other, but a conflict between whole peoples, a conflict between two separate and distinct theories of government, of civilization, even of existence itself. That advertising does play this important part in such a conflict as the one that has held almost the entire world in its grip for nearly three years is no theory. It is no bombastic utterance; it is plain and sober fact. It has been proved without any shadow of possible doubt, and this brings me perhaps in a roundabout way to the subject that stands against my name in to-day's programme, "What Advertising Has Done for England." What advertising has done so far may be tabulated very briefly:

It raised four million fighting men under the voluntary system.

It raised countless billions of dollars in loans floated in England.

It raised nearer $200,000,000 than $100,000,000 in private donations for the various war charities, the majority of which were and are still being run by advertising men.

It discovered to the authorities over a million men whose trades and their knowledge of those trades made them skilled munition workers.

It persuaded over a million women to offer their country the labor of their hands to release the male workers for other duties.

Advertising taught the people of Great Britain to work harder and produce more, to give up their useless luxuries when it was necessary to consume less petrol, less rubber and less food; it taught the British people the sin of waste and the glory of sacrifice.

WHAT WOULD HAVE HAPPENED WITHOUT ADVERTISING.

Now there is always a great danger in overstatement, and in case there are those who might say that I am "drawing the long bow" in making these claims for advertising, let me say straight away that I do not claim that advertising accomplished all these things by itself. The war itself is bigger than advertising; naturally, and it was the occasion, the tremendous occasion, that counted. But consider what would have happened without advertising. What would have been the position of the Allies six months after the war started? What would have been the position a year afterwards? What would have been the position to-day?

We can only come to a judgment of these questions by negative speculation. It is perhaps a clumsy method, but it is the only method available, and such as it is I propose to employ it.

You must remember that while these great advertising campaigns were in progress the Allies were on the defensive; they were just holding on. Every man, every shell, every gun, every munition worker, every woman worker counted enormously. Imagine what would have happened in that terrible year of 1915 had there been a really serious shortage in men and money, in addition to the temporary shortage of munitions.

During those fateful days of 1915 a shortage of 50,000 men on the Western front, especially at the second battle of Ypres, would have meant disaster to the British army. The British generals were short enough, God knows, but not too short to hold the line. Thanks to advertising, the men were there in sufficient numbers, and thanks to their heroism, the line was held.

Again take what the shortage of munitions meant in those same months, when every projectile was worth its weight in solid gold. What happened then? There was formed the great Ministry of Munitions. That ministry, with Lloyd George at the head of it, bought land and factories and iron and steel, but what was the good of all this material without the men to work and weld it into guns and shells? The men were there; they were in England somewhere. The problem was to find them and take them from the cycle factory, the piano works, from any place, in fact, where men were used to work in metal, and to collect them and parcel them out to man the factories that were waiting to receive them. That was no easy task. How was it accomplished?

One of the first appointments made in the new Ministry of Munitions was that of advertising director, who advertised for the men and got them, and a few months afterwards the men at the front were no longer short of munitions and never have been since. Advertising never yet made a shell or a fuse or a cap or an ounce of picric acid, but it delivered into factories easily, without friction and quickly, all or nearly all the available men who could do these things. Supposing that the government had decided not to try the advertising experiment, supposing that the government had been forced, in those dark days when for a whole year not one solitary item of good news reached the British people, to raise the men for the front and the men for the back of the front by other means.

Imagine what would have happened had the government been forced at that time to introduce some measure of conscription of fighting men, of working men and of capital. That the country would have ultimately risen to the occasion I have, of course, not the slightest doubt, but there is also no room for doubt that such legislation would have met with the greatest opposition and the energies of the nation would have dissipated in a domestic political strugle with what result I dare not even suggest.

Without advertising there would have been volunteers in their hundreds of thousands, without advertising capital would have been forthcoming in millions, but men were needed, not in hundreds of thousands, but in millions, and money was needed, not in millions, but in billions; the people did not know what they were up against—it was the business of advertising to make them understand.

WHAT SUCCESS OF WAR LOAN MEANT.

I do not think, however, that it is necessary for me to spend any more time in proving that advertising did all, and more than all, its advocates claimed that it would do. The fact is that in England it has been employed to accomplish, easily and quickly, do not forget that last word, *quickly*, each and every purpose of the government. Perhaps, however, I may be permitted to refer to another campaign, especially as a similar campaign is now being launched in this country. I refer to the campaign conducted on behalf of the second war loan late in 1915. If I remember rightly, it was a three-billion-dollar loan. It was not the intention of the government to advertise this loan, and the usual "peace time" single-column spaces were issued to the newspapers. I remember my astonishment at seeing the old familiar column in *The Times* one morning, and you may depend upon it that I didn't waste much time in getting in touch with the official government agent. I remember, also, his alarm at my suggestion that the loan should be advertised like bags of flour or tins of tobacco. I may tell you now that in that first week the loan was a failure. It was not that the people were not patriotic, but the days were too big for the old methods, and in the crash of events at the front the old sterotyped announcement was lost.

As it was, the loan was about to be a failure, and would have been a failure had not the government taken the suggestions of the little group, the little group of willing men, who were advising on advertising generally.

Assume that the government had decided not to advertise the loan and the three billion dollars asked for had not been forthcoming, what would have happened? In the first place, the British Empire would have lost credit throughout the world, the men in the trenches across the Channel would have been disheartened, not to say disgusted, and the enemy would have every grounds for claiming that the strongest and richest member of the Entente was quitting. As it was, something quite different happened. The loan was heavily advertised and easily and *quickly*, to be precise, in fourteen days after the advertising started, the loan was over-subscribed; and, instead of being partially discredited in the eyes of her Allies and in the opinion of the world, instead of giving comfort to the enemy, Great Britain was able to encourage her soldiers, cement the alliance and deliver a blow to the powers arrayed against her.

It is needless for me to remind you that in this war political and moral considerations are almost equal to those of purely military significance, and the success of the second war loan was as great a victory to the Allies as the capture of a fortress on the Western front. As a matter of fact, it was the only positive victory that the Western Allies had that year.

It was not always easy to persuade the various departments of government to allow us to aid them. My own experience was limited to the Admiralty, and I shall never forget my first interview with the shy and retiring, though gallant, men who lurk in the dark chambers of that edifice. On that ocacsion I felt almost as scared as I now feel. I had elaborated my plans for increasing recruiting at some length, and when I had concluded a distinguished Admiral said, "Are we to understand, sir, that you desire to *boom* the navy in some manner?" to which I replied, "That, Admiral, would be my purpose." There was a short silence, then the gallant sailor replied, "You are evidently not aware, sir, that the Royal Navy is known as the silent service."

After the experience (on the second war loan), however, there was no need for us to have to persuade the authorities as to the value of advertising. As I have said, it has been employed ever since for every purpose that the government has sought to accomplish.

In the "Iron Grip"--But Too Hard to Hurt
SKF
BALL BEARINGS
Only a dent in the vise—that's all. The Crucible Steel Balls used in S K F Ball Bearings are so hard and resilient that they will not crush under this most severe test.
If you try to crush a ½" S K F Ball by squeezing it in a vise, you would have to exert a pressure equal to a load of 33,000 lbs. Literally, they are a tower of strength and hardness.
When you want a bearing that is strong, wear-proof,—specify S K F. Our Engineering Service Department will gladly give you information about S K F for your machines.

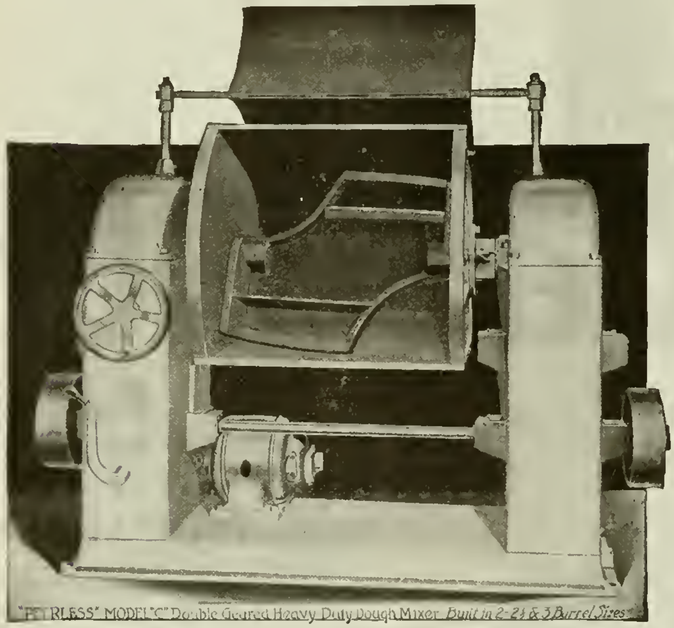
The Johnson Friction Clutch Is Being Used As A Part Of This Machine



Courtesy The Peerless Bread Machine Co., Sidney, Ohio.

Mixing Dough

is the vocation of this machine and the mixer is controlled by JOHNSON FRICTION CLUTCHES installed on the horizontal shaft and two Johnson clutches are used, one in each of the vertical columns. You know how Mother mixed her bread. You know how careful she was not to overknead it. The same is true with automatic mixers. The mixer must knead the bread to a certain consistency and then the Machine is stopped through the use of JOHNSON FRICTION CLUTCHES.

This installation is but another instance of Johnson Friction Clutch Satisfaction.

For Your Own Machines—

Have you thought of incorporating clutches? You know that people are known by the company they keep. So are all other things. Have you noticed the machines the JOHNSON FRICTION CLUTCHES are associated with? Let us introduce you to clutch satisfaction, THE JOHNSON FRICTION CLUTCH, so your machines may become acquainted. Write us about your requirements to-day.

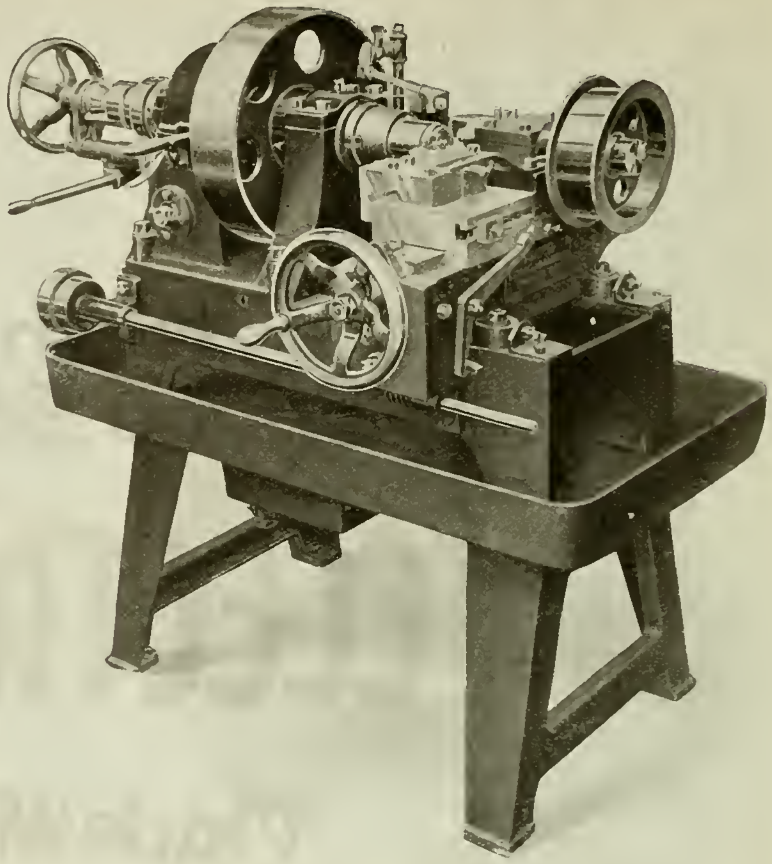
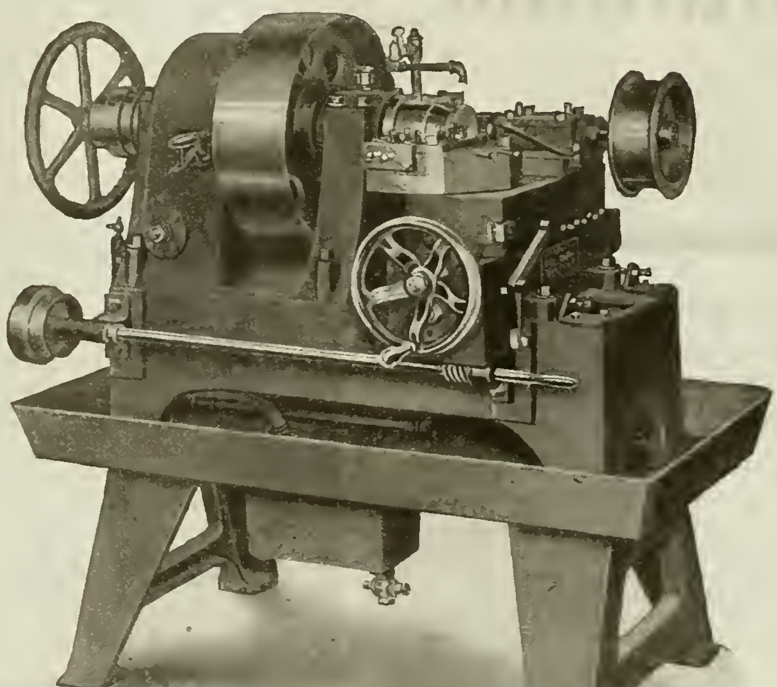
THE BANFIELD THREAD MILLER

For Milling inside and outside threads on Brass or Steel Sockets for Nose of 4.5--60 pdr., 6-in., 8-in. and 9.2-in. Howitzer Shells.





THE BANFIELD PLUG MILLER

Patented in Canada and United States

THIS machine is especially designed for finishing base plugs, turning the outside diameter, finishing the face with any camber desired, and milling the thread, all in one chucking, the complete plug being finished in six minutes by unskilled labor.

The machine is equipped with quick draw in collet. Drive pulley 18" x 6", with bronze bush having cut jaw clutch for turning and facing. Worm gear 100 to 1 ratio with cut jaw clutch for milling, driven by 10" x 1½" flanged pulley. The milling cutter is driven by an 8" x 2½" flanged pulley. Tool post carriage is equipped with power feed (two speeds) having automatic stop. Power feed pump with relief valve driven from worm shaft (all drives direct from main line shaft). Rigidly built, simple and economical to operate.

Weight 1,800 lbs.

For 18 pdr., 4.5 and 60 pdr. High Explosive Shells. Can furnish machines of same type, but somewhat lighter in construction. Particulars on request.

These machines are tooled up for finishing plain machined or beveled plugs, if desired.

Write for prices and deliveries.

Prompt Shipment

For Turning, Facing and Milling the thread on Gas Check Plugs for 6-inch High Explosive Shells.

BUILT EXCLUSIVELY BY

The Reason
For So Many Repeat Orders

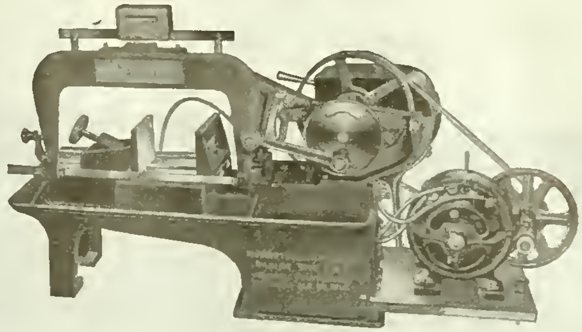
after comparative tests is that no magnifying glass is necessary to distinguish the increased production and the better class of work on the PEERLESS High-Speed Cutting-off Saw.

A third order just came in from one of the largest concerns in the United States, and is it not a fact after a firm has standardized on a certain make of tool that some real results must be produced in order to effect a change?

One of our customers writes: "It takes us only 1-15th of the time to cut our stock on the PEERLESS that it did on our other machine."

If you are open to conviction we have a proposition to offer that no manufacturer can afford to pass up.

PEERLESS MACHINE CO. 1607 Racine St. RACINE, WIS., U.S.A.



We will send a Racine on a Trial Basis—*Why?*

The Racine machine is the only high-speed metal-cutting machine in the world that is absolutely positive in every action, and will duplicate itself in every cut during the entire life of the machine. All wearing parts are adjustable and accurately machined.

Hamilton Lathes

Is Your Cost of Production too high?

In the well-managed factory there is no greater loss of time—and therefore of money—than that resulting from the use of old style machinery.

All over the country shops are now running at top speed, and producing more for the dollar than ever before. Why? Because they are installing modern machine tools—tools built to withstand all the strain put upon them by the use of high speed tool steel.

You cannot expect to meet the competition of to-day with the methods of yesterday. To-day your equipment must be of the best, otherwise your costs will go up as your production goes down.

Investigate "HAMILTON" Lathes, put them in your factory—then watch the balance swing the other way. Speed, durability and accuracy are the points that make "HAMILTON" tools indispensable in cutting your cost of production.

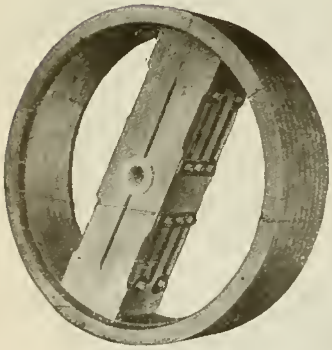
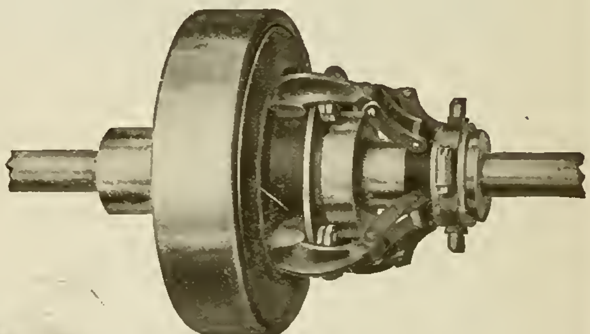
The Positive Clutch & Pulley Works, Limited

THE PRODUCT



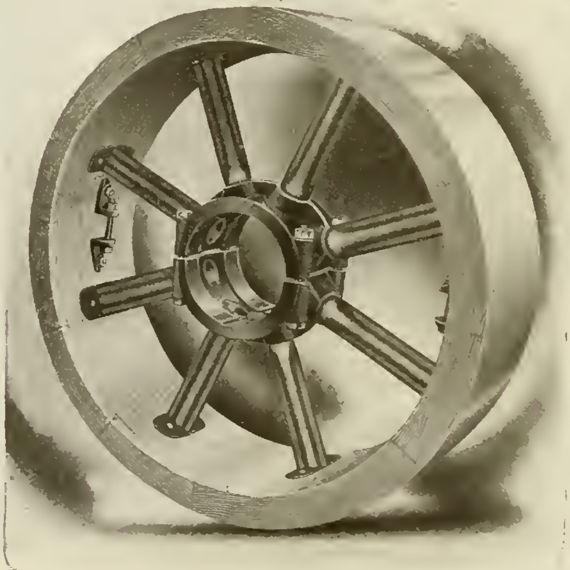
You cannot beat THE STEEL TRUST. But the Positive Wood Split Pulley will save every year $3.00 that each metal-faced pulley costs you in belt slippage.



Positive Clutches

Save Belts
Save Time
Save Labor

Equip your machines with Positive Clutches in place of Tight and Loose Pulleys, which rapidly wear out and cannot be engaged quickly.



When you order Positive Wood Rim Steel Centre Pulleys you secure all that can be claimed for the Steel Pulley or the Wood Pulley, without the disadvantages of either. You will gain much by immediate action. We are now equipped and supplied ready to complete your requirements. Remember the three: "Positive Clutch," "Positive Wood Split Pulleys," "Positive Wood Rim Pulleys."

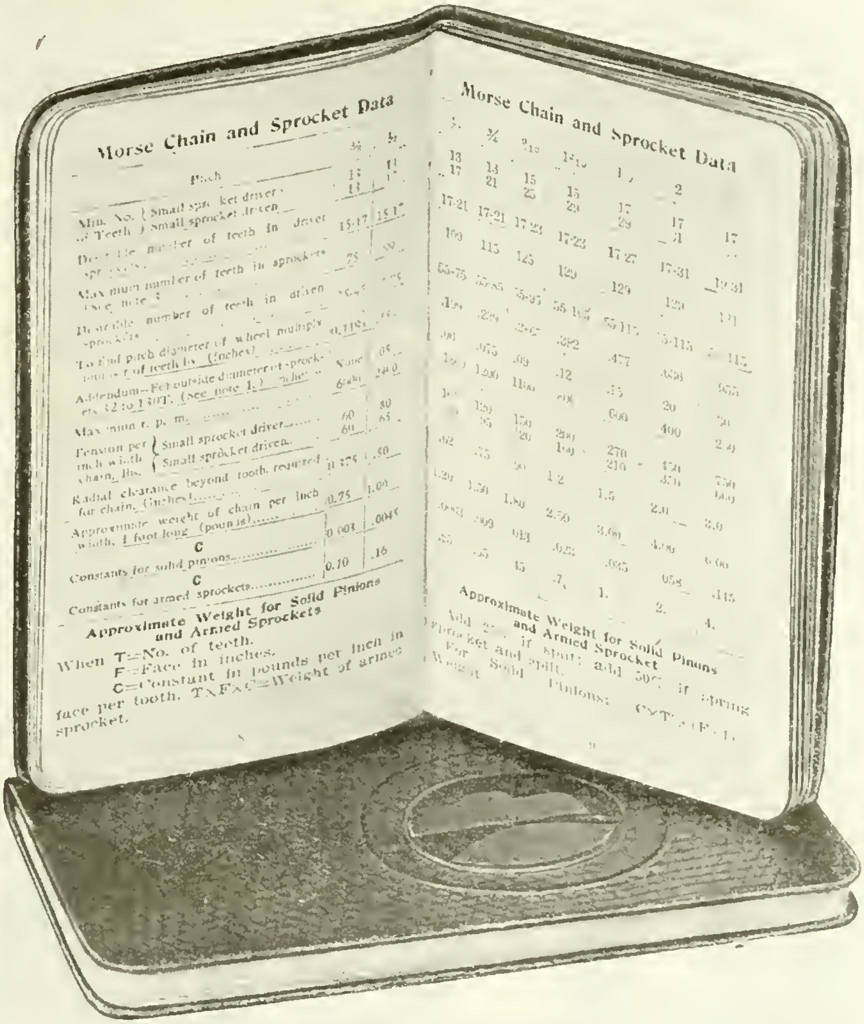
Last Call for the Diary

(of 1917)



THE Morse Chain Company 1917 Diary is a diary in name only, the memorandum pages not being dated as in previous years. The book therefore does not get out of date as the year draws to a close.

Eighty $2\frac{1}{2}$ by $4\frac{1}{4}$ plain ruled pages, in addition to 48 pages of MORSE Chain Data and Illustrations, bound in genuine black leather, make a book but $\frac{1}{4}$ inch thick and just the right size for the vest pocket.

Over 6000 of these little Memo and Data Books have so far this year been distributed to manufacturing plant men in the following positions:

PRESIDENTS
VICE-PRESIDENTS
SECRETARIES
SUPERINTENDENTS
PURCHASING AGENTS
MASTER MECHANICS
MANAGERS
ELECTRICAL ENGINEERS
MECHANICAL ENGINEERS
MINING ENGINEERS
AUTOMOBILE ENGINEERS

In other words, we have given the book without charge or obligation of any kind to those to whom the data would be of value and who hold positions of authority as regards the purchase of equipment.

Only about 500 of the books are still available, and if you desire a copy we suggest filling out the coupon below and forwarding it to-day—to-morrow may be too late.

FOR FERTILIZER GRINDERS

AGRICULTURAL CHEMICAL WORKS
901-903 Macy Street,
Los Angeles, Calif. 10/7/16.

Magnolia Metal Company,

Gentlemen: Referring to your inquiry regarding Magnolia Metal would say that the same is satisfactory in every way and does all you claim for it. Since we began using this brand we have had practically no trouble with hot bearings, and can recommend it as the very best for high speed machinery.

We are running a fertilizer grinder at the rate of 1500 revolutions per minute, which at times creates considerable dust, and have had no occasion to re-babbitt the bearings since the last two years. This surely speaks for itself.

Yours truly,
AGRICULTURAL CHEMICAL WORKS,
By L. Baruch, Sec'y.

PRACTICAL ENGINEER POCKET BOOK:
Over 600 pages. A valuable reference work imported from England and sold as an advertising medium at the low price of 40c post paid.

SURROUND YOUR BUSINESS WITH NEVER-FAIL BELTING
DUNLOP BELTING
SEAL OF QUALITY
"GIBRALTAR"
"Strength of Gibraltar," while not our phrase, aptly applies to the rubber belting made by us and sold under the name "Gibraltar Redspecial."
* * *
It would be interesting to us if you, as a user of belting, would, before making your next purchase, get a verdict on "Gibraltar" from some of your friends.
* * *
Ask them if a stronger belt than "Gibraltar"—one giving more service with less loss of power—can be obtained anywhere; if any other product will survive heavy loads better; and, if, in withstanding the jerky strains consequent on fluctuation of power, any other belt can show a higher quality of friction in uniting the plies than "Gibraltar Redspecial."
* * *
We have evidence aplenty, in the form of voluntary testimony, which shows that for strength, durability and general service "Gibraltar Redspecial" is matchless. In the Biggest Saw Mills, Biggest Pulp and Paper Mills, Biggest Manufacturing Plants, one "driving force" is nearly always in evidence—Dunlop "Gibraltar" Belting.
* * *
For Drives, Rotaries, Edgers, Lath and Shingles Machines, or any kind of Transmission work, there is nothing better than Dunlop "Gibraltar Redspecial" Belting.
* * *
And what Dunlop "Gibraltar Redspecial" means to users of Transmission Belting, Dunlop "Samson" ensures to users of Conveyor or Elevator Belting.
NO LOAD TOO HEAVY
DUNLOP "GIBRALTAR" BELTING
NO SERVICE TOO EXACTING

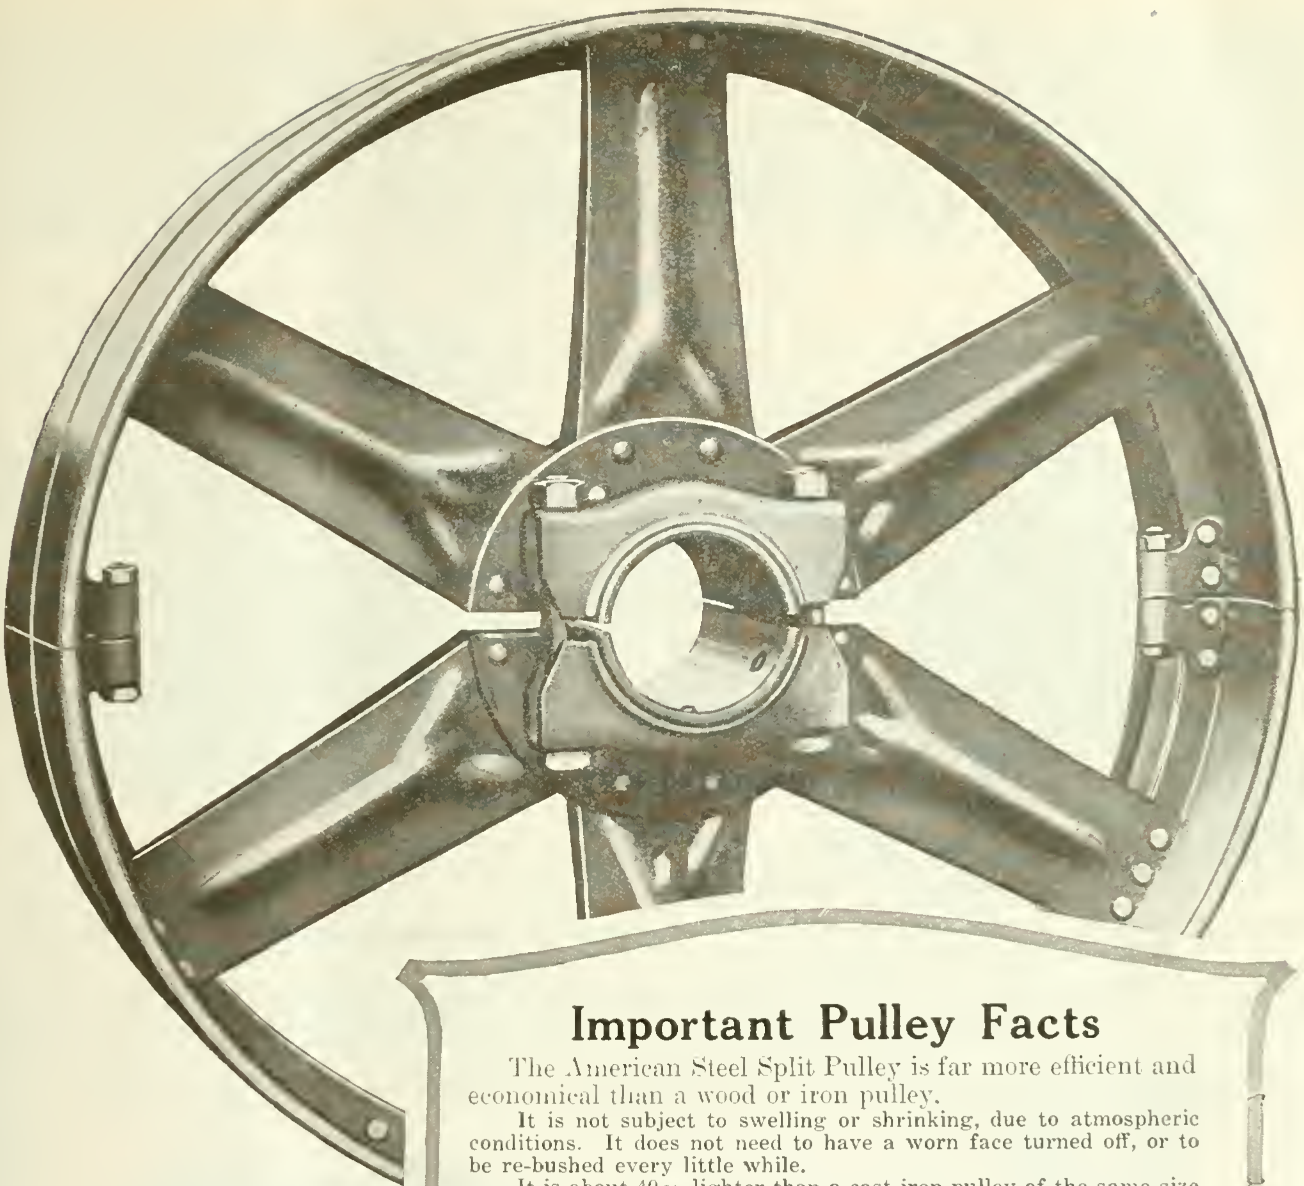
DUNLOP TIRE & RUBBER GOODS CO., Limited



Important Pulley Facts

The American Steel Split Pulley is far more efficient and economical than a wood or iron pulley.

It is not subject to swelling or shrinking, due to atmospheric conditions. It does not need to have a worn face turned off, or to be re-bushed every little while.

It is about 40% lighter than a cast iron pulley of the same size and its steel face holds a belt with much less belt-slip than a cast iron face. This is very important, for belt-slip is a constant leak and loss of power.

AMERICAN STEEL SPLIT PULLEYS

"Americans" are guaranteed to perform double belt duty under all ordinary conditions. They will endure higher speeds than any other standard metal pulley. Their flat A-braced arms cut the air and reduce wind resistance to a minimum.

Write for the free book—"Pulley Efficiency," and you will know why American Pulleys are big money-savers—why there are over three million in use—more than of any other one make.

THE FORD TRIBLOC

Good Reading on Good Hoists

A success is always worth reading about. Especially so when it is of the Longfellow variety—the kind that attains the heights by forging ahead while others slumber.

There's a big idea behind the success of Ford Tribloc Chain Hoists. The idea of getting better service out of a hoist by putting better materials and features into it. All-steel working parts, non-gagging LOOP Hand Chain GUIDE, planetary type of spur gearing—those are some of the meritorious features of Ford construction.

They are worth reading about in detail in our new Catalog. How shall we address it?

Ford of Philadelphia

FORD CHAIN BLOCK & MANUFACTURING CO.

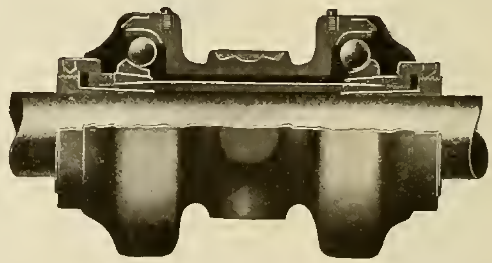
LESS FRICTION—LESS POWER LOSS

There is 75% Less Friction with



Chapman Double Ball Bearings

A factor of well recognized importance in a shaft hanger is Power Cost. Power cost goes up with increased friction. Friction in a well designed ball bearing is far less than in a sliding bearing. Then since Chapman Double Ball Bearings are designed solely for transmission purposes, users save 75% of friction loss in transmitting power.

Use of Chapman Ball Bearings means a saving in oil, a saving in labor of oiling and general attention required in Babbitted shaftings—and they are thoroughly dust-proof.

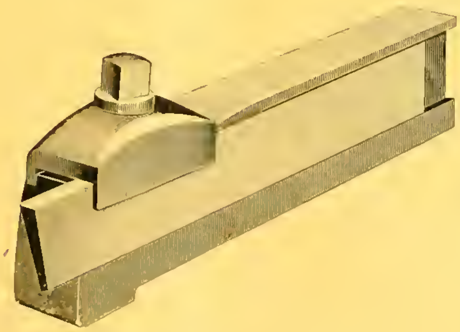
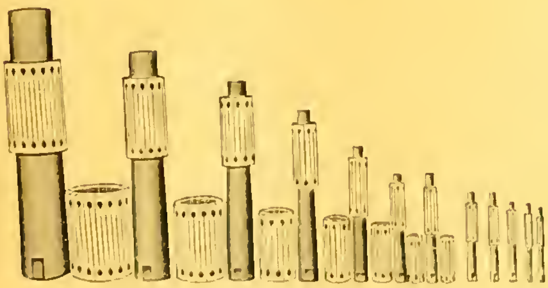
Machinists' Necessities

"Champion" Turning Tool

"Champion" Boring Tool



"Champion" Cutting-off Tool



"Champion" Expanding Mandrel

CHAMPION tools are economical both as to actual cost and operation. Our expanding mandrels cost about one-sixth the price of solid arbors of equal range. When you take into consideration the time consumed in looking for an arbor and the difference in the cost, the economic feature is all one-sided. The quality of the tools are up to the "Champion" standard.

The cutting-off and turning tools are above the ordinary. They are "Champion" quality.

An inquiry would demand our immediate attention and co-operation.

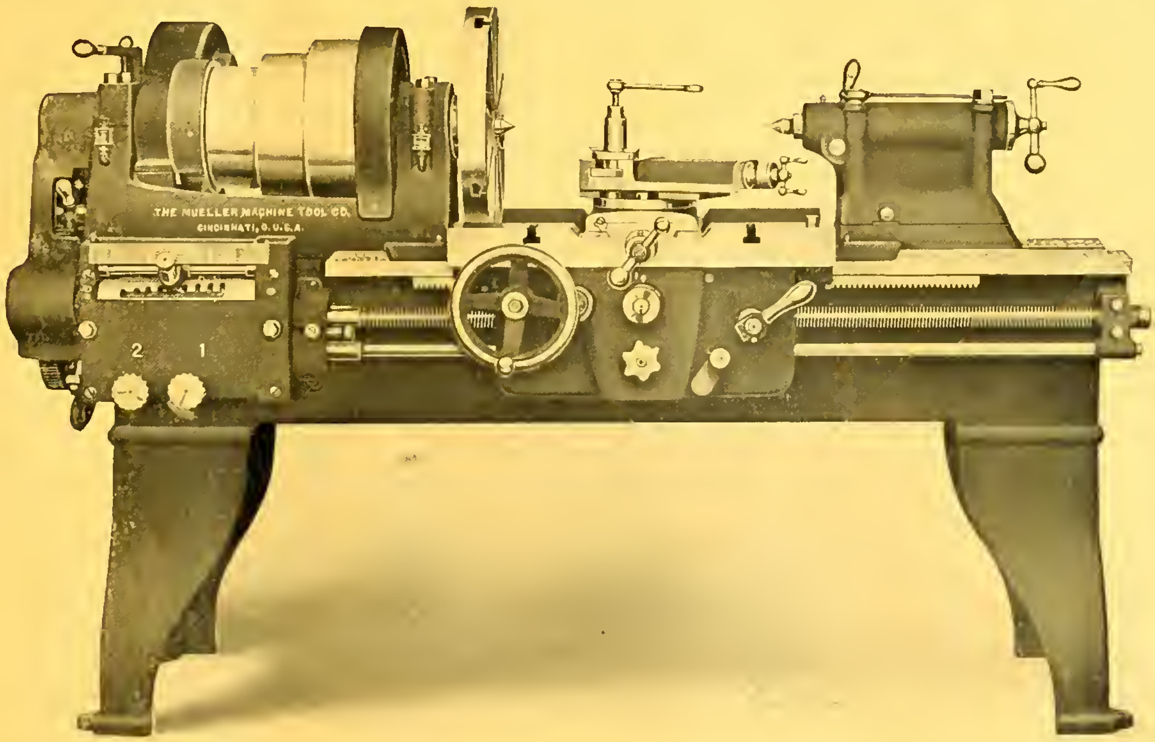
The Mueller Engine Lathe

18-Inch Standard Heavy Duty Type



There's a growing demand for a medium size lathe that can handle manufacturing and general shop work with accuracy, speed and profit—a rapid, rigid, wide-range lathe—and to meet these requirements we offer the 18" Mueller Engine Lathe.

The keynote of Mueller construction is rigidity. It is insured by an exceptionally deep bed, stocky legs, heavy head and tail stocks, spindle provided with heavy steel thrust collars and means for taking up wear, long spindle bearings, and by a general guarding against the inroads of hard usage. On the Mueller 45 threads can be cut with changes obtained within the gear box; there are 18 spindle speeds.

The Mueller Engine Lathe is adapted for light or heavy cuts, high or low speeds, for literally ripping off stock or chasing a fine thread, and in addition, handles a wide variety of work *without special attachments.* Operation is simple, convenient and safe.

For economical reasons investigate Mueller advantages before you buy lathes.

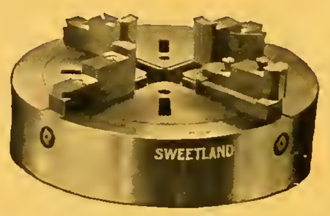
Sweetland Combination and Universal Trucks

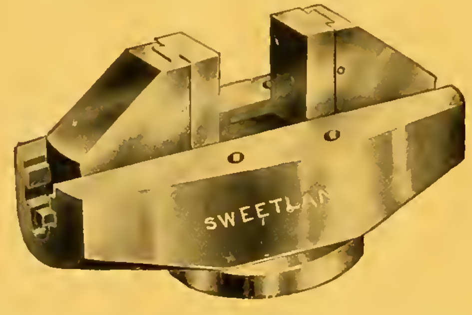
Made with Three or Four Jaws



A "Combination" Chuck is one in which the Jaws can be operated either independently or universally, as desired.

On account of the simplicity and completeness of its interchangeability from the independent to the universal operation of the jaws, or *vice versa*, and the unusual strength of this Reversible Jaw, this Chuck is acknowledged by all practical mechanics as being the best Geared Screw Chuck made. Furnished also with solid jaws, non-reversible, either inside or outside bites.

We put up the same style Chucks, both Three and Four Jaws, *without the Combination Attachment.* With this exception it is practically the same chuck as our Combination, thus making a first-class *Universal* Chuck. The jaws are ground *perfectly true on face and bite, after being hardened.*



THE SWEETLAND BOX BODY CHUCKS

With Soft Steel Slip Jaws

Tool Steel and Soft Metal Slips, or Special Jaws of any kind can be furnished when required.

Furnished either as Universal or Independent as desired. In the Universal the hole through the Chuck is, of course, obstructed by the screw which operates the jaw.

HAND CUT STEEL LETTERS, FIGURES, STAMPS AND MARKING ROLLS

LETTERS AND FIGURES

The proper grade of steel is used in the construction of these hand cut steel figures and letters. A size suitable for the letter to go on it is used, and is long enough so it can be held without hitting the fingers.

HAND CUT STEEL STAMPS

Of all kinds and for all purposes. The work is all strictly hand cut, the letters being correctly shaped and the stamps properly tempered to suit the work they are to do.

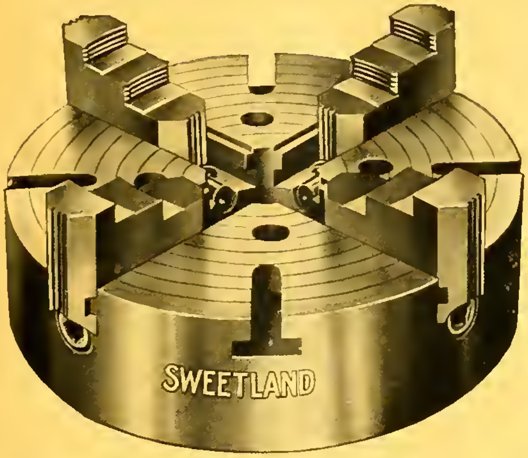
MONTREAL

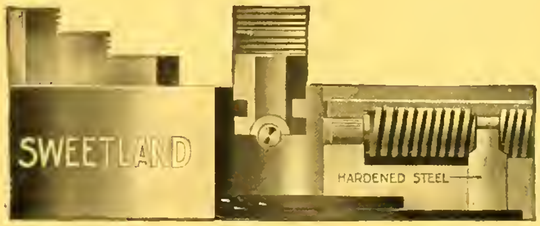
The FOSS & HILL MACHINERY Co.

305 ST. JAMES ST., MONTREAL, QUE.

Sweetland Independent Lathe Chucks

Iron and Steel



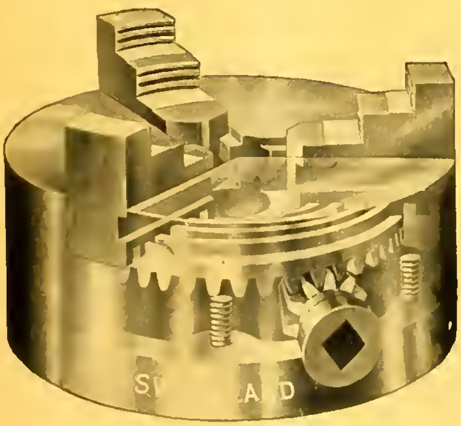


Body neatly designed, strongly built and properly balanced. Maximum strength with minimum weight.

Hardened steel bearings, screws, large and well made, of a special grade of steel, flush with body of chuck.

Jaws of a good grade of steel, properly hardened. Gripping and bearing surfaces ground perfectly true, reversible.

The Sweetland Geared Scroll Chucks



This Chuck is made in sizes 2½" to 18" diam., both with Three and Four Jaws.

When so ordered it is supplied with Solid Reversible Jaws, two sets in one. A unique feature in a Scroll chuck.

It is also fitted with non-reversible inside or outside Jaws, or with both sets, as may be specified.

Material and workmanship throughout are of the best.

The jaws are ground perfectly true on face and bite, after being hardened.

Plenty of Coolant at Slow Speed

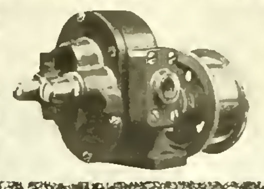

Figure 1854.

TRAHERN ROTARY GEARED PUMPS can be operated at slow speed and yet furnish the desired amount of coolant—this is not possible with a centrifugal pump, which must be run at terrific speed to supply enough lubricant to the cutting tool. This naturally shortens life of the pump. With TRAHERN positive drive you can force sufficient lubricant through discharge to reach deep bores or other work difficult to cool—an accomplishment peculiar to the geared type. These are but some of the reasons why such machine tool manufacturers as The Gleason Works, Gisholt Machine Co., etc., are equipping their machines with TRAHERN product. We want to tell you all about them.

Send this page with your address noted on it and we will.

The Value of a Clean-Cut Layout

Unless work is laid out accurately at the start, many difficulties will arise as the job progresses.

A confusion of faint lines may mean lost time and perhaps throwing away a valuable piece of metal.

It is important then that the lines be distinguished quickly, no matter how much they crisscross. The clean-cut lines made with a

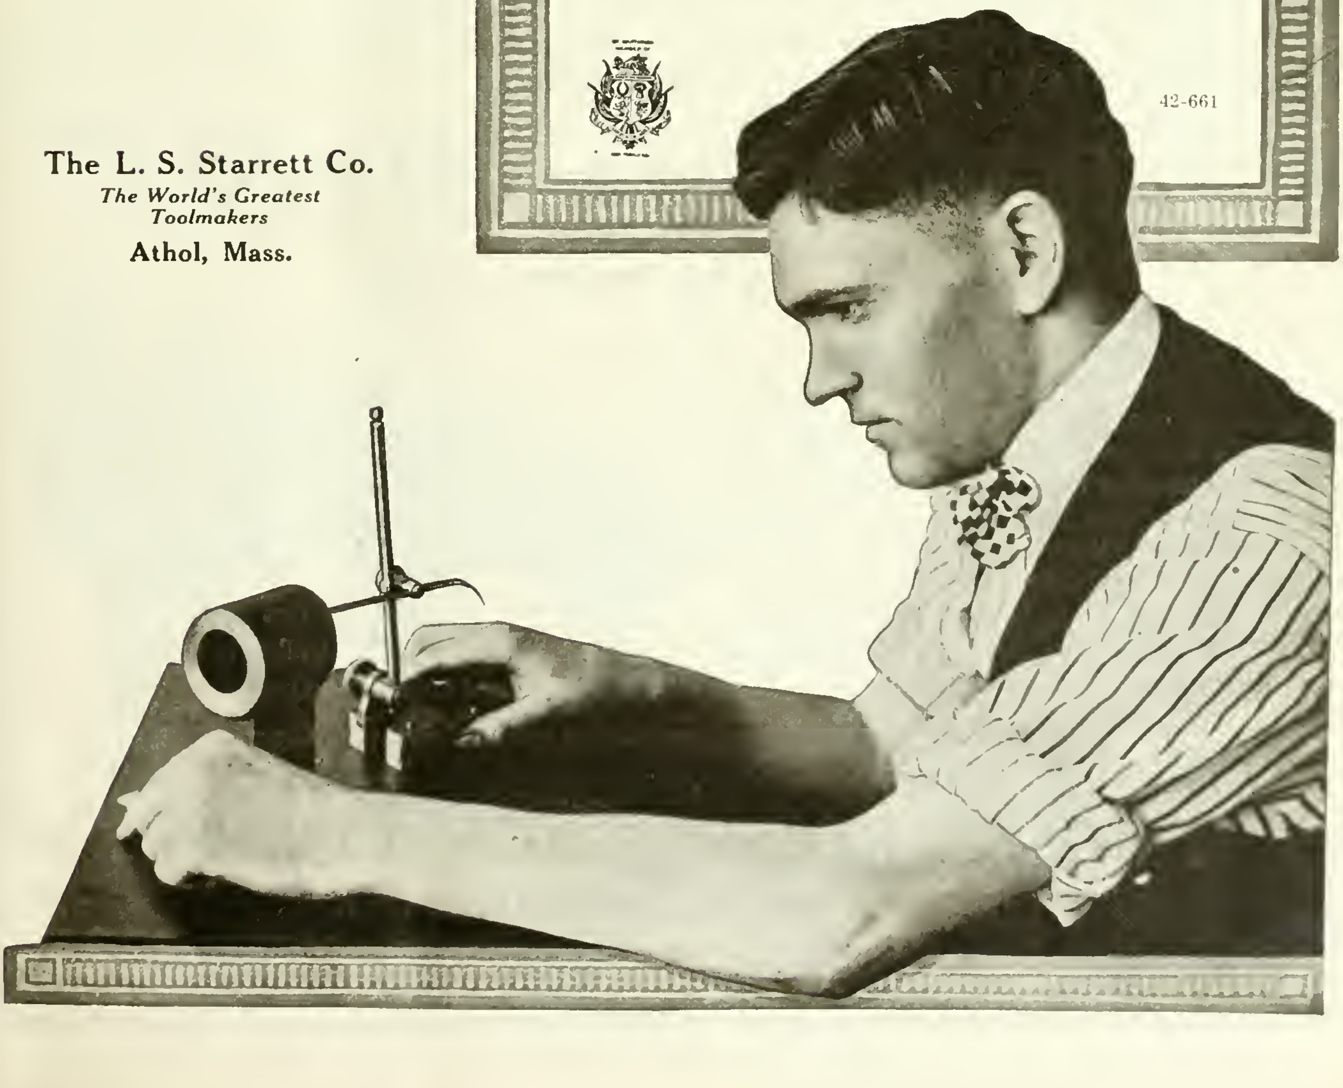
Starrett
Surface Gage

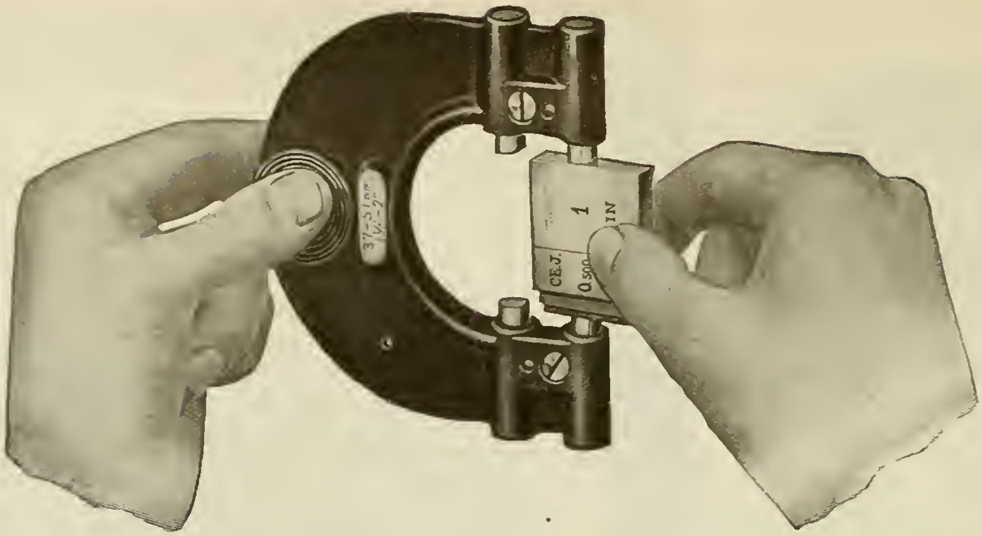
will greatly aid machinists in preparing a clean layout on which work can be done accurately. This useful instrument may be used to scribe on all kinds of surfaces and is very handy for transferring measurements for duplicating work.

Our free catalog No. 213 will tell you more about this surface gage, also describes 2,100 sizes and styles of measuring tools. Write for it to-day.

42-661

The L. S. Starrett Co.
The World's Greatest Toolmakers
Athol, Mass.





Tools That Increase Production

Two hands and ten fingers, to-day, can produce a great deal more than they could a thousand or even a hundred years ago. We all know why.

Science, taking form as machinery and tools, has multiplied the usefulness of our two hands. Modern tools and scientific methods give us greater power to help ourselves and to serve others.

A good tool appeals to the pride of every workman. It puts him on his mettle. It gives him a new sense of responsibility for first-class work.

THE JOHANSSON
GAGING SYSTEM

Johansson Standard Gages are used in every civilized part of the world to originate sizes and establish limits. They are invaluable for setting and checking all kinds of gages and measuring tools. They simplify the work of laying out jigs and fixtures—thus saving valuable time. They reduce waste by preventing mistakes due to inaccuracy.

Johansson Adjustable Limit Shop Gages bring the limit system within the reach of all. With a "Johansson" limit gage, the operator doesn't waste time *wondering* whether his work is right. He can test both limits at one touch without even turning his hand. Faster and easier work, with greater security that the product will be "just right."

Johansson Limit Gages are adjustable for wear, changing limits and different sizes. It would pay to compare the cost of "Johansson" equipment with the endless expense of making up and maintaining your own gages.

If you want to increase your production adopt Johansson Gages.

THE SWEDISH GAGE CO., Inc.

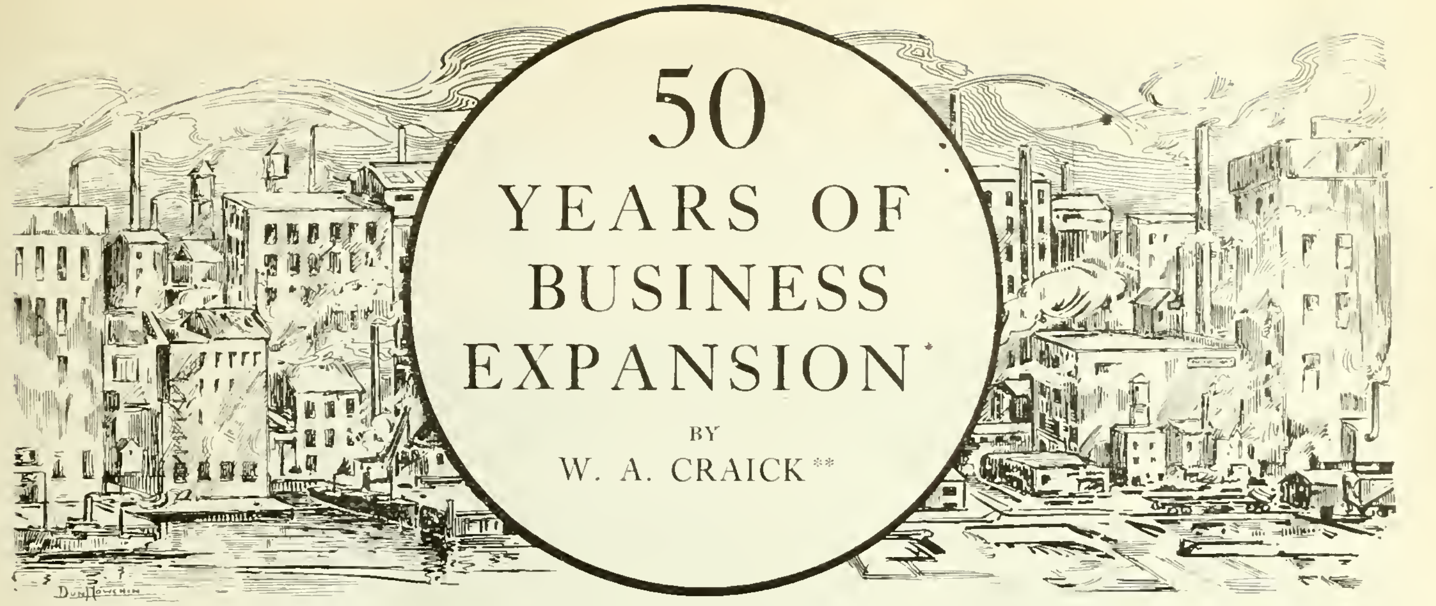
INDEX TO ADVERTISERS—Continued from page 227



50 YEARS OF BUSINESS EXPANSION*

BY

W. A. CRAICK**

There is here given in racy fashion, yet evidencing in the variety detail discussed considerable painstaking and scrupulous regard for developments in the period under review, to the end that as far as possible everything embraced by the article title, wide in scope as it happens to be, should get at least a passing reference. Speaking generally, the advances made in the spheres of Industry, Finance, Transportation and Insurance are prominently featured.

CANADA'S position at the close of the fiftieth year of Confederation is imposing only in so far as present day conditions are placed in contrast with those prevailing at the dawn of the Confederation era. Progress is at best a relative term, and to appreciate to the full the extent of this country's development, one must visualize the setting in which that development was commenced.

To all intents and purposes, the whole of Western Canada, with its far-flung population, its many fine cities, its thousands of miles of railway and its enormous agricultural production, must be eliminated from the canvas. It is true that by 1867 some ten thousand people had settled in the Red River Valley; that stragglers had penetrated even farther west. It is also true that the gold rush of the late fifties had poured population into the Fraser River Valley and that Victoria was already a fair-sized town. But these widely-separated settlements, on the prairies and at the Coast, were almost as distant from Eastern Canada in those days as Australia is to-day, and further, their business associations were entirely with the neighboring sections of the United States.

Canada in 1867

The picture of Canada in 1867 narrows, therefore, to the comparatively restricted limits to the older settled portions of the country—the narrow fringe of clearing along the St. Lawrence; the lake front counties of Ontario; the coast and river settlements of New Brunswick and the scattered towns and fishing villages of Nova Scotia. The wider vision of a great and prosperous West had not yet seized upon the minds of the people and their field of possible endeavor lay no further off than the thickly wooded concessions of the back counties.

Though fairly well populated and supplied with the modern means of communication, the older sections of Quebec and Ontario were still in a comparatively crude and undeveloped condition. Even between Montreal and Toronto, then as now, the two foremost centres of population in Canada, the appearance of the country was anything but prepossessing. There remained much uncleared land. Many of the homes of the inhabitants were at best but miserable shanties. The people were poor; the children dirty and ragged; the cattle lean. Towns, which were quite as numerous as they are today, and in several cases nearly as large, were suffering from the after-effects of the Grand Trunk boom, and exhibited numerous unoccupied and delapidated buildings.

From Prescott to Ottawa, then the customary route to the Capital, the railway traversed what appeared to be a continuous pine swamp, wet, dismal and depressing. The Capital itself lay hidden away in the midst of green, unbroken forests, which closed in on the log houses and small villas lying on the outskirts of the embryo city.

To the rear of the counties fronting on the St. Lawrence and Lake Ontario, settlement was just getting under way at the time Confederation came into being. Railways were being promoted to tap the resources of Peterboro, Victoria, Simcoe, Grey and Bruce Counties, and settlers were arriving from the Old Country to people their solitudes. In fact, this particular section of Canada was going through an experience which has since been duplicated many times in the West.

The Government was devoting special attention to the settlement of the free grant lands in the Muskoka District. Advertising matter of the same brand as that which later lured thousands of immigrants to the prairies, told of the prospective wealth to be derived from the cutivation of the soil in this remote part of the province. In response to the appeal, population was penetrating as far north as Parry Sound on the shore of the Georgian Bay, while Bracebridge was thronged with newcomers.

Oil and Gold Booms

It was about this period, too, that the oil boom in Enniskillen Township and the gold boom at Madoc were absorbing public attention. The former attracted the curious from all parts of the country. To reach the oil fields, visitors had to leave the Sarnia branch of the Great Western at Wyoming and drive through the woods to Oil Springs. It was a trip, as described by travelers, full of spectacular interest. The great dark forest, traversed by a narrow plank road; the constant succession of carts coming and going with their barrels of oil; the derricks, oil tanks and engines scattered through the clearings, all presented a scene of strange and outlandish character. Oil Springs itself was a village of wooden hotels, thronged with speculators and hangers-on, who by their frenzied efforts to secure paying properties increased the popular interest in the district.

The Madoc gold finds were made in the year before Confederation and the rush to the mines in the spring of 1867 was one of the events of that momentous year. Prospectors in lare numbers thronged to the new gold fields, from which so much was expected, and many miners, who had participated in the California and British Columbia rushes, made their way to the new Eldorado. Five lines of stages from Belleville to Madoc

*Also in MacLean's Magazine.
**Of MacLean Publishing Co. Staff.

were for a time insufficient to accommodate the crowd who sought access to the scene of the discovery.

These events, bulking largely in the popular imagination at the time, have long since dwindled into their proper proportions. The oil wells of Enniskillen have become a commonplace; the gold strikes at Madoc have sunk into insignificance. Reference has been made to them merely to illustrate how places which fifty years ago were on the very fringe of settlement and to reach which tedious journeys had to be made, are now left far in the rear by the tide of progress. The gold of Porcupine has long since eclipsed the gold of Madoc, and in Southern Alberta the oil prospector has been finding new fields for his investigations.

Lumbering

In various other respects conditions have changed in old Ontario and Quebec. Lumbering was a far more important industry fifty years ago than it is to-day. The Great Western Railway brought down from its Sarnia branch annually large quantities of oak timber. This wood was rafted at Hamilton and towed to Quebec for export to the Old Country. The Northern Railway carried to Toronto, and the Port Hope, Lindsay and Beaverton Railway hauled to Port Hope trainload after trainload of lumber for shipment by schooner across the lake. Cordwood was one of the commonest commodities of the day, and trainloads of it were a common sight on the railroads fifty years ago. It was used not only for heating and cooking, but it formed the universal fuel for locomotives, and from the back settlements thousands of cords were shipped annually to the United States.

Early City Settlements

The extent of settlement in 1867 was reflected in the cities. To-day there are in the Dominion six cities with populations in excess of 100,000 — Montreal, Toronto, Winnipeg, Ottawa, Hamilton, and Quebec—while a seventh, Vancouver, falls little short of that figure. In the year of Confederation, however, Montreal was the only urban centre that came within 50,000 of reaching the 100,000 mark. Toronto could not boast 50,000 inhabitants. Winnipeg was a mere hamlet. Ottawa contained but 15,000 people. Hamilton just exceeded 20,000 by a narrow margin. As for those flourishing Western cities—Calgary, Edmonton, Regina, Saskatoon, Brandon, Moose Jaw, and Vancouver—they were practically all non-existent. Only conservative old burgs like Quebec, Halifax, and St. John, had populations in any way commensurable with present figures.

LUMBERING ON THE UPPER OTTAWA. A FLOURISHING INDUSTRY AT THE TIME OF CONFEDERATION.

Our Capital City

The beautiful capital city of the Dominion, whose natural charms have been greatly enhanced by the work of the Ottawa Improvement Commission, has developed during the fifty years of Confederation from a crude backwoods settlement into one of the finest cities in America. So unprepossessing was its appearance when it was selected by Queen Victoria to be the seat of government, that it was described as the Cinderella of Canadian Cities. Its intrinsic beauty was recognized, but that beauty was so hidden by uncouth and dirty surroundings that the comparison was by no means inapt.

Curious visitors who went to view the new capital during the early sixties, came away with mixed impressions. It was admitted that the site of the Parliament Buildings was a lovely one; that the surrounding forests had a wild impressiveness, and that the clear air, everlasting resounding with the noise of falling water, was exhilarating, but what were these natural attractions when everyday living conditions were so bad? The streets were rough, the houses mean and squalid, the hotel accommodation wretched, and the food poor. Lumber and sawdust littered the place until it looked like one vast timber yard.

A sister of Lord Monck, who visited the town shortly before the Governor-General moved there from Quebec, groaned over the prospects of life in such a place, describing it as "t'other end of nowhere." And it is known that civil service employees, who had to forsake the comparative loveliness of Toronto, Montreal, or Quebec, for its early crudities, bemoaned their fate, while Ministers of the Crown took the earliest opportunity to escape from its impenetrable dulldullness.

Of course, all this has changed. Ottawa to-day boasts the possession of every modern facility, not only for the enjoyment, but for the improvement of life. Its beautiful streets and parks, its splendid public buildings, its superior hotels—all these combine to render the contrast with the miserable, down-at-the-heel settlement of fifty years ago most striking and complete.

And what of other cities? Montreal,

the foremost city of the Dominion with its more than 600,000 people could, in 1867, muster barely one-sixth of that number. In extent it was very considerably smaller. Its principal business thoroughfare of to-day, St. Catherine Street, lay on the outskirts of the city. Even lordly St. James Street, with its splendid financial institutions, was only just in course of construction. Business centred in Notre Dame Street; McGill College stood out in the suburbs, and it was a mile walk from the edge of the city to the mountain.

In several respects, Montreal, fifty years ago, was greatly inferior to the present city. Its streets were notoriously filthy, especially along the docks where the mud frequently lay knee-deep. The lighting even of the main thoroughfares was inadequate, gas being then the universal illuminant. The drainage was bad, and in this connection one visitor tells of having to leave the Theatre Royal one night in the middle of an amusing comedy on account of the vile odors that were wafted in through the windows. Apart from these deficiencies, however, the city seems to have been an imposing place with its solid-looking buildings, its many fine churches and its active commerce.

Our Queen City

Toronto's expansion during the fifty years has been equally, even if not more, phenomenal. When it is recalled that in 1867 Queen's Park, now in the heart of the city, was on its extreme northern edge, Trinity College was situated a mile beyond the western limits and that troops were able to go through extensive evolutions on a great common that lay between the city and Spadina Avenue, some faint conception of the physical growth of the place can be obtained. In population it has increased twelve-fold, or roughly from 40,000 to 480,000.

The cities in the east, Halifax and St. John, have probably exhibited fewer changes than their western sisters. Halifax, which has now about 50,000 inhabitants, had a population of 30,000 at the time of Confederation. St. John, which to-day contains approximately 54,000 people, was then a place of 35,000 inhabitants. In Halifax the lives of the citizens revolved around the garrison of British regulars which manned its forts and citadel. Some trading, it is true, went on with the West Indies. Fish was exported; sugar and other tropical products imported. But the military and naval interests of the place predominated and trade and commerce, while a necessary evil, were not allowed to thrust themselves too far into the foreground.

The commercial spirit was more in evidence in St. John, a city which then as now regarded its Nova Scotia contemporary with a feeling of suspicion and rivalry. St. John had been a notable shipbuilding centre for years and, not only was many a stout vessel built each year in its shipyards, but its merchants owned and outfitted numerous deep sea craft for service on the seven seas. The docks of St. John were a busy spot in those days, for ships and sailors were numerous and there was a constant coming and going of vessels from distant ports.

Industries Feature

If cities were small fifty years ago, so also were the industries that flourished in them. Industrially, there has been a remarkable change in Canada during the past half-century. When Confederation came into being the settled sections of the country were plentifully supplied with an immense number of small steel industries. Each town, each village, had its little group of manufacturing establishments which produced the essentials of life for the people of the immediate neighborhood. A flour and grist mill, a sawmill, a tannery, a carding and fulling mill, a carriage factory and not infrequently a brewery or distillery were the possession of practically every centre of population.

The census of 1861 showed that in Ontario alone there were in operation 501 flour and grist mills, 1,164 sawmills, 271 tanneries, 185 carriage factories, and 143 breweries and distilleries. In Ontario, Quebec, New Brunswick, Nova Scotia and Prince Edward Island combined, there were 8,503 industries, of which 1,785 were flour and grist mills, 4,240 sawmille, and 710 tanneries. By 1867 all these figures had probably been considerably increased.

Few of these primitive local industries have survived the evolution of the centralized factory system. Here and there through the country there may remain some pathetic examples of these once important institutions. But, generally speaking, the economies introduced in the operation of the large factories of to-day have made it quite impossible for the small industry to exist.

Lachine Canal an Industrial Factor

Even in the sixties there were evidences of the development of large-scale manufacturing. The building of the Lachine Canal seems to have produced a considerable industrial boom in Montreal. The canal furnished four million horsepower of hydraulic energy per annum, a huge figure for those days, and, as practically all manufacturing was done by waterpower, manufacturers naturally flocked to this new source of energy.

The extent and importance of the factories along the canal filled visitors with astonishment. There were huge iron works, employing no fewer than 120 men and producing 12 tons of nail plates per day! There was a wonderful new flour mill, which could grind 500 bbls. of flour in twenty-four hours. There was a sugar refinery with a capacity adequate to manufacture seven-eighths of the sugar consumed in Canada and there was a marine works, which could produce several ships for river and lake service each season.

One may smile at the expressions of amazement with which the citizens of 1867 regarded these examples of industrial enterprise, the size and output of which have long since been eclipsed by immensely larger establishments, but, after all, there were some industries in operation fifty years ago which would astonish even the wonder-sated folk of the twentieth century. The sawmills at Ottawa, for instance, were undoubtedly marvels. There were ten of them running night and day in an endeavor to keep pace with the efforts of the ten thousand lumbermen who were busy felling the forests along the river. One of these mills boasted eighty saws and the others were very little smaller. The ten mills together turned out 180,000,000 feet of lumber a year, while 16,000,000 cubic feet of square timber was rafted to Quebec each season for shipment across the Atlantic. In that golden age of the lumber trade, it took 800 ships, manned by 25,000 men, to carry the harvest of the Ottawa from Quebec to England.

Wood Shipbuilding

These were great and picturesque enterprises and so, too, was the wooden shipbuilding industry, which was in its heyday of prosperity when Confederation came into being. At Quebec and at many a harbor and port on the coasts of New Brunswick and Nova Scotia, fine, large wooden vessels were built and launched annually in considerable numbers. There were fifteen shipyards at Quebec alone, in which from 25 to 50 ships were turned out each year. Unfortunately, except for a forced revival of the industry at the present time, wooden shipbuilding is dead and thus an interesting chapter in Canadian industrial history is closed.

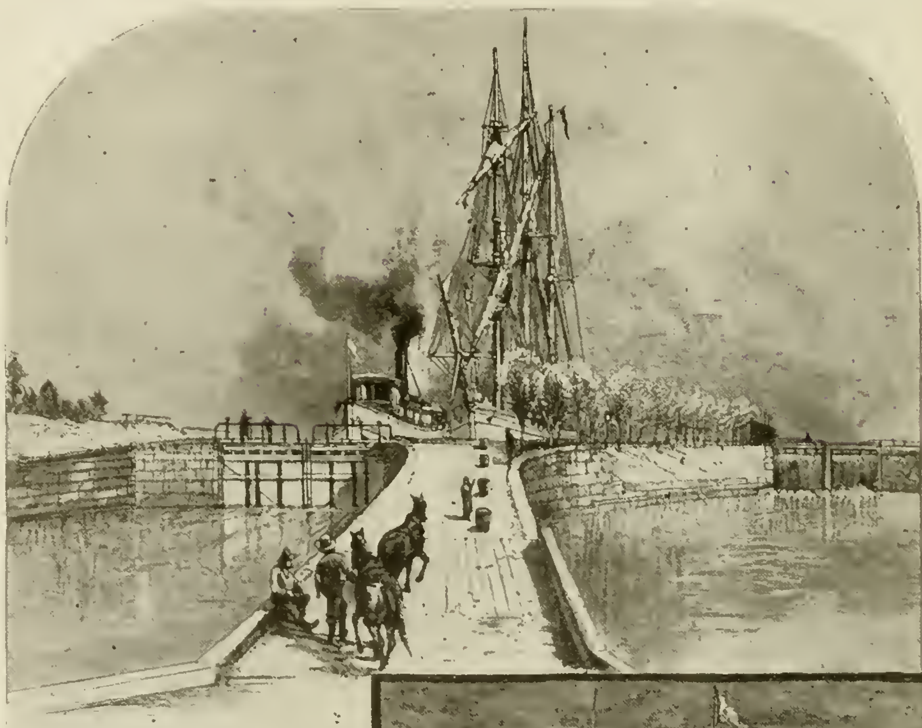
However, all industry in Canada in and about the year of Confederation was not so spectacular, though to the people of the time many of the developments seemed very wonderful. In Hamilton, for instance, where foundations for future industrial greatness were even then being laid, it was deemed a remarkable feat on the part of the local manufacturers to have installed $100,000 worth of new machinery in a single year. The production of locomotives at Kingston was considered a work little short of marvellous. The erection in Sherbrooke in 1866 of a woollen factory five stories high was heralded as a most important event, while Victor Cote's new tannery at St. Hyacinthe, which gave employment to 90 hands, was regarded as a mammoth plant.

But if industries were small and scattered, the products of industry were by no means inferior. At the great Paris Exhibition in 1867, the goods of Canadian manufacturers showed to advantage. Furniture made by Jacques and Hay in Toronto was declared to be superior to anything on display. The wall hangings of the Stauntons compared favorably with the product of the English makers. The Barbers, of Streetsville, showed cloths and woolens of most creditable quality. Implements from the Jones plant at Gananoque and the Whiting plant at Oshawa, were highly commended, as were also the cigars exhibited by Davis, of Montreal.

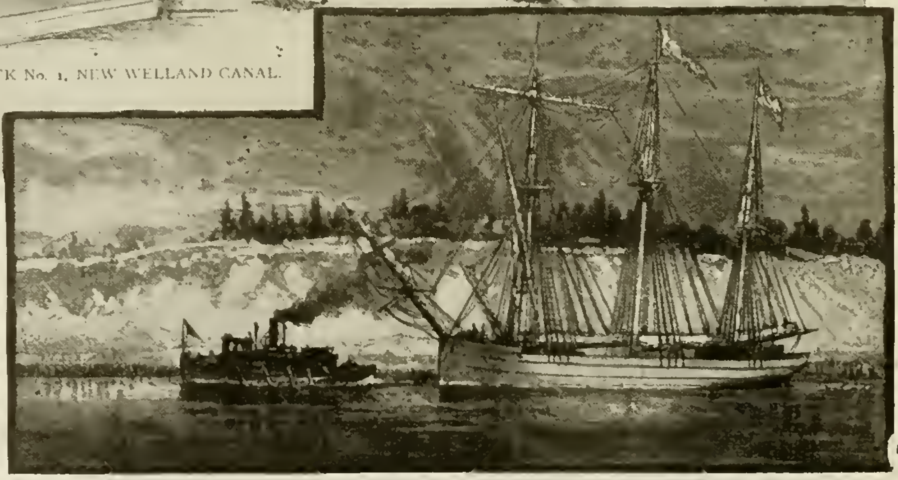
Transportation Developments

Industrially, Canada has traveled far since those far-away days. All the marvelous expansion which the introduction of electricity has facilitated has come since then. The mammoth textile works with their electric drives; the great steel plants; the huge paper mills; all these and many more have sprung into being since 1867, and in no respect has the progress of Canada been more marked than in this department of national life.

Hand in hand with the growth of industry has gone the extension of transportation facilities and rapid means of communication. In 1867 the railway systems of the country, since expanded into transcontinental proportions, were limited in scope. This was especially true of the Maritime Provinces, where the stage coach was still an established and very necessary institution when the Confederation era dawned. Nova Scotia was served by two short lines of road, running from Halifax to Truro and from Halifax to Windsor respectively, a matter of some hundred miles of track in all. New Brunswick likewise had but two railways, one connecting St. John and Shediac and the other St. Andrew's and Woodstock. Prince Edward Island, which has now a system of 275 miles, was without any railway at all. In short, the three Maritime Provinces among them had only about 300 miles of road in operation, whereas today their mileage extends to 3,668 miles.



LOCK No. 1, NEW WELLAND CANAL.



THE DEEP CUT, A VIEW OF THE WELLAND CANAL IN THE EARLY DAYS.

The Upper Provinces were somewhat better served. The Grand Trunk, then the longest railway in the world under one management, ran from Portland, in Maine, to Sarnia, in Ontario, and from Riviere du Loup, on the Lower St. Lawrence, to Richmond, P.Q. Its most formidable rival was the Great Western, running from Niagara Falls through Hamilton, to Windsor, with a branch from Hamilton to Toronto. Northward stretched lines from Prescott and Brockville to Ottawa, from Port Hope to Beaverton, and from Toronto to Collingwood. All the rest of the network of roads now traversing both old and New Ontario were non-existent.

Railroad Through Traffic

The idea of through traffic was only just being evolved in 1867. The Great Western, then a wide-gauge road, as were most of the railways in Canada, had laid a third rail from Windsor to Niagara Falls and built a car ferry for service across the Detroit River, in order to secure a slice of the business between the newly developed settlements in the Middle West and the seaboard. The Northern Railway from Toronto to Collingwood was paying so much attention to the traffic it was receiving from the upper lakes and trans-shipping at Toronto for lower lake ports, that settlers along the line complained of the difficulty of getting their cordwood shipped to Toronto. In fact, the promoters of the Toronto & Nipissing and the Toronto, Grey & Bruce made it a point in soliciting financial aid from the municipalities that they would serve the settlers better in this regard that they were receiving.

Communication between the Maritime Provinces and the Upper Provinces in those days was usually by coasting vessel from Halifax or St. John to Portland and thence by Grand Trunk to Montreal. The extension of the Halifax-Truro road to Pictou, completed in the Confederation year, gave a new summer route up the St. Lawrence to Quebec, while one of the fruits of the new political arrangements between the provinces was the establishment of a line of steamers to run from Montreal and Quebec to Maritime Province ports. Otherwise it was possible to take a longer stage journey up the St. John valley from the railway terminus at Woodstock to Edmundston and across the height of land to Riviere du Loup, where the Grand Trunk terminated. This was the route by which the British regulars journeyed to Upper Canada at the time of the Fenian scare.

Victoria Tubular Bridge

The recent completion of the Victoria tubular bridge at Montreal was then filling the minds of visitors with awe and astonishment. It was hailed as one of the wonders of the world, a scientific achievement without a peer in the history of construction. Its three million cubic feet of masonary, its eight thousand tons of iron, its enormous length, its great cost, were dilated upon in unmeasured terms of admiration. For the times it was indeed a remarkable engineering feat, but since then many a far more wonderful undertaking has been completed in Canada, which illustrates still further how the country has progressed.

Canada's canal system had by 1867 reached considerable proportions and comparatively speaking, traffic by water was of more importance than that it is to-day. The lakes were covered with sailing craft, while steamboats were far more numerous than they are now. Of course, all these vessels were so much smaller than the big freighters of the twentieth century that mere numbers were insignificant. At the same time they provided a most picturesque element in the picture of Canada in 1867. The passage of fifty schooners a day through the Welland Canal was by no means an unusual experience in the year of Confederation.

The canals were much smaller than they are to-day. Those on the St. Lawrence, by means of which ships passed up from Montreal to Lake Ontario, contained but nine feet of water, while the locks were limited to 200 feet in length. Notwithstanding this, records of vessels are not uncommon which had sailed down from the upper lakes and, passing through these canals, had later crossed the Atlantic.

Conditions of Travel

Traveling conditions in the year of Confederation were none too satisfactory. As compared with the luxury of the present day, a journey even for a short distance was an arduous and uncomfortable undertaking. In the Maritime Provinces, if a traveler preferred an overland journey instead of a trip by coasting vessel, he would have to put up with the inconvenience of a wearisome ride in a big, lumbering, springless stage over rough roads, his only solace the occasional pauses for rest and refreshment at old-fashioned change houses. In the Upper Provinces, he would have to contend with the wretched service of what were referred to at the time as the most poorly conducted railways in the world.

Two trains a day in each direction were sufficient to accommodate the traffic between the two largest Canadian cities. One made the journey by day, the other by night, and the run was scheduled for something like fourteen hours. The locomotives burned wood and there were frequent stops en route to re-load the tenders. Cars were small and light, the track poorly laid and the bumping and jolting terrific. One wretched tourist who endeavored to beguile the telium of the journey by a game of draughts found to his disgust that it was quite impossible to keep the men on the board.

Postal System

The postal system in Canada fifty years ago differed very little from the present system except that very much higher rates of postage had to be paid, and it took much longer for letters to reach their destination. The rate to points in Canada, that is, Ontario and Quebec, was five cents; to the United States, 10 cents, and to England, 12½ cents. A special weekly service to Halifax, via Portland, having been arranged, a business man in Toronto or Montreal could send a communication to Nova Scotion for the sum of 12½ cents. As for British Columbia, it cost 25 cents to forward a letter to the Pacific Coast.

Statistics for the year 1863 show that there were in the Upper Provinces, 1,974 post offices in that year and that the number of letters carried was 11,000,000. New Brunswick had 375 post offices, in which 833,625 letters were handled, and Nova Scotia 493 post offices, with 1,467,726 letters. The year's revenue for the three provinces was $853,778, and the expenditure, $896,303. As an indication of the extent to which the postal service has since expanded, it may be said that in 1915, the revenue for all Canada was over thirteen million dollars and the expenditure nearly sixteen millions.

Telephones

While the telephone was unknown in 1867, the telegraph and the Atlantic cable were both in existence, and so far as telegraphic communication was concerned, Canada was well served. Indeed, in Nova Scotia the boast was made that they had more lines of telegraph per inhabitant than in any other country in the world and, what is even better, lower rates. In Ontario and Quebec, the Montreal Telegraph Company, with over 3,000 miles of wire, controlled the situation, while in the Maritime Provinces the lines, about 2,000 miles in extent, were controlled by the American Telegraph Co. As there are to-day over 200,000 miles of wire in the telegraph systems of the country, it is obvious that here again there has been vast development.

The story of the telephone is all contained within the limits of the Confederation era. There were no telephones when Confederation was born. To-day there are between six and seven hundred thousand instruments in use, with over a million and a half miles of wire connecting them.

Electrical Street Railways

Electric street railways have been another modern development. In fact, in the year of Confederation, horse cars had only just come into use. Toronto's system had been opened in 1861. It consisted of six miles of track on Queen and Yonge streets, with eleven cars and 70 horses, a total investment of only $175,000. Montreal had also about six miles of track with similarly small equipment. Halifax was a third city with a system of horse cars at that time. The innovation was not welcomed. One critic complained that "the street railway is an institution for the benefit of those who ride, at the expense of those who drive, and is a flagrant violation of the rights of the majority. The horse railway is a permanent obstruction; it practically divides a wide street into two narrow ones and a narrow one into two lanes. It is questionable whether it will be found profitable in Canada."

In the light of this hostile attitude, it is interesting to note that the tiny systems in the three leading cities of 1867 have since developed into a vastly important series of electric lines, located in practically every city in Canada, operating upwards of 1,700 miles of track and carrying annually six hundred million passengers. The capital invested in them amounts to over $150,000,000.

Trade and Finance

Trade and finance have shown marvelous expansion in the fifty years of Confederation. When it is considered that in 1868 the country's total trade only amounted to a little over $131,000,000, of which $57,500,000 represented exports; that the export of manufactured products in that year scarcely amounted to $2,000,000 and agricultural products exported were under $13,000,000 in value, then the growth becomes all the more remarkable, for, in 1916, Canada's trade amounted to nearly a billion and a half dollars; her exports of manufactured products to $242,000,000, and her exports of agricultural products to $250,000,000. Her mineral exports in the same period jumped from $1,800,000 to nearly $67,000,000, and the products of her fisheries from $3,500,000 to over $22,000,000.

The development of trade has been graphically reflected in the expansion of the financial institutions of the country, notably the chartered banks and the insurance companies. There were as a matter of fact, more banks doing business in 1867 than there are to-day, but the banks of the Confederation year were very much smaller and, in several cases, they were in a notoriously shaky condition. In all, there were twenty-six of them in existence, with a paid-up capital among them of approximately thirty millions, or about a quarter of the paid-up capital of the twenty-one institutions now operating under Dominion charters. There were about 120 branches doing business, the large majority of which were located in the Upper Provinces.

Since 1867, sixteen of the twenty-six chartered banks on the list in that year have disappeared, either through failure or amalgamation, leaving but ten of their number to carry on the traditions of the pre-Confederation days. The survivors, in point of age, are the Bank of Montreal, Bank of Nova Scotia, Bank of British North America, Bank of Toronto, Molson's Bank, Bank Nationale, Merchants Bank, Banque Provinciale, Union Bank, and Canadian Bank of Commerce. Eleven new banks have been established, bringing the present total up to twenty-one.

To-day Canadian banks have over 3000 branches in Canada alone, not to mention agencies in the United States, the West Indies, and elsewhere. Their assets have grown since 1867 from seventy-five millions to well over two billions; their liabilities from forty millions to over eighteen hundred millions. They have deposits of over fifteen hundred millions as compared with twenty-five millions fifty years ago, and their circulation has expanded in the half-century from nine millions to over $132,000,000.

Insurance

Life insurance was the smallest of Canada's financial institutions in 1867. Only one Canadian company—the Canada Life, which had been organized in 1847—was operating, and the total insurance in force of all companies, including British and American, did not exceed $30,000,000. Progress in this one business alone has been little short of phenomenal. Company after company has been organized until to-day no fewer than twenty-six domestic companies are reporting annually to the Dominion Department of Insurance, not to speak of fifteen British and sixteen American companies.

By the end of 1916, the insurance in force on the lives of Canadians amounted to nearly a billion and a half dollars, of which nine hundred millions was carried by our own Canadian institutions. The latter, whose assets in the year of Confederation were a mere bagatelle, now show accumulated wealth approximating three hundred million dollars; their annual income runs to over sixty million dollars; while they disbursed last year to policyholders or to their beneficiaries nearly twenty-five million dollars in cash.

The business of fire insurance has enjoyed a similar expansion. Our Canadian companies, then few in number and uninfluential, had at risk in 1867 about fifty million dollars, on which they were receiving premiums of somewhat less than half a million dollars and paying losses of from a quarter to half a million dollars a year. Last year, the domestic fire companies had $663,758,129 at risk, on which they were receiving premiums of nearly five million dollars, while they met losses during the year of over half that amount.

One might proceed and produce figures bewildering in their detail to demonstrate how far Canada has progressed in every department of business activity since 1867. The tremendous expansion of agriculture due to the opening up and settlement of the West; the development of mining, which is placing Canada in the forefront of the mineral-producing countries of the world; the growth of the fisheries; the extension of hydro-electric power in industry; these and a hundred other matters might easily be referred to as affording means of gauging the country's fifty years of progress. However, enough has been written to give a faint idea of the Canada of fifty years ago and with this in mind it is not difficult to picture mentally the extent of development.

COAL SITUATION IMPROVING

C. A. McGRATH, controller of Canadian Fuel Supply, has returned to Ottawa from Washington, where he has been consulting with the American fuel controller, Mr. Peabody. Mr. McGrath says that the American authorities are dealing with the fuel situation in the thorough manner in which the difficult problem requires. They have opened a bureau and obtained the services of mining and transportation authorities. Mr. McGrath states that at Washington he found a friendly feeling for Canada and a disposition to deal fairly with the Dominion in the matter of fuel with which he is concerned. Mr. McGrath does not think that Canada will have any great difficulty in obtaining the quantity of anthracite required, if the transportation companies are able to distribute it promptly to the points in the Dominion where it is required.

The supplying of bituminous coal presents a more difficult problem. Mr. McGrath says that he requires immediately a precise statement of bituminous requirements of Canada for the coming winter. He desires every Canadian consumer of bituminous coal immediately to write him at Ottawa, stating the quantity of coal he had been consuming and the quantity he will require during this summer and the coming winter. Total quantities and the monthly requirements should be stated. Any consumer who wants to ensure his supply is advised to state his requirements without delay and state them accurately and honestly.

WOOD SHIP CONSTRUCTION IN BRITISH COLUMBIA.

SHIPBUILDING IN CANADA

By A. W. Robinson*

THE question of shipbuilding is an urgent one at the present moment. Steel vessels cannot be built promptly because the steel mills are sold out for ship plates nearly two years ahead and because skilled labor and shipyard equipment are also short and cannot be created quickly. We are therefore reviving the art of wooden shipbuilding and meeting with some success, especially on the Pacific Coast.

There are difficulties also in building wooden ships, among which are: First, skilled labor accustomed to the regular practice is scarce and not equal to the tonnage required; second, our sawmills turn out straight lumber, whereas the construction of ships, especially in their frames, requires many curved and irregular-shaped pieces, which it has been the ancient art of wooden shipbuilding to produce; third, the lumber available is unseasoned and will shrink and not make a good job when done. It seems to me, therefore, that the question should be taken up anew in the light of present conditions and requirements, and that we should not attempt to build a wooden ship on exactly the old lines or in the old manner.

Composite Construction Suggested

In making studies on the question, I have come to the conclusion that a composite construction would meet the case better than steel alone or wood alone. We can obtain steel angles and channels for the frames and also straight lumber in ordinary merchantable sizes. We can also get a certain number of handy woodmen and laborers who, though they cannot be classed as ship carpenters, could do plain work of this kind under instruction.

My suggestion is, therefore, that the vessels be built with steel frames, made of plain merchant sections, with a minimum of curved work, and that the remainder of the vessel, consisting of the beams, keelsons, deck planking and side planking, be made of wood in plain straight pieces as far as possible.

A vessel built in this way would, in my opinion, be more economical, both in first cost and in operation than an all-wooden ship, for several reasons, as follows:—

1—Very few curved wooden frames are required.

2—The work could be done largely by ordinary labor, under proper supervision.

3—The ship would be stronger than an all-wood ship.

4—It would have a greater cargo-carrying capacity as compared with the all-wood ship, on account of the reduced size and space required for the frames.

5—The fastenings of the woodwork to steel frames by means of screw bolts would be more secure than the old-fashioned drift bolts and spikes used with wooden frames, and could be tightened up as the wood shrinks.

6—The ship could be built more promptly and be a better job when done.

Evolution and Revolution in Machine Shop Practice

By J. H. Rodgers *

Conjointly with the production of munitions came the demand for machine tools, creating a situation that required the utmost resources of the country and the greatest ability and initiative of our whole engineering profession, individual and collective. The results of such a circumstance have been reflected in attainment of hitherto undreamt-of achievement.

THE remarkable growth of metal-working industries during the past three years has undoubtedly been the outstanding feature of an otherwise abnormal period of activity, not alone in Canada, but in every other country in the world. While it is true that the primary cause of the development gives cause for regret, it has nevertheless been the means of opening the eyes and clearing the vision of communities and nations who had too long been oblivious to the gathering clouds that threatened the future peace and welfare of the entire universe; morally, socially and commercially.

During the early months of 1914 Canada had experienced a period of severe depression which became somewhat aggravated immediately before, and for a time after, the opening of hostilities. The almost universal belief that war between two great civilized countries like England and Germany was practically impossible kept the vast majority of people in an optimistic state of mind, and we, too, it may be said, were struck with amazement when the event actually happened. The depression that had been so pronounced a few weeks before became almost a panic when the sudden entrance of Britain into the maelstrom of Europe was definitely announced, and the predominating feature throughout the entire country appeared to be the complete disorganization of every line of activity. Fortunately, however, the "stage fright" was of short duration, as we then began to realize more clearly the magnitude of the possibilities that the early future might have in store for us. The first to awake were the masses of our citizens themselves, this being reflected in the anxiety for news of European developments, hope being still strong that actual hostilities might somehow in the end be prevented. This craving for information resulted in greatly increased activities in certain directions; telephone companies, newspaper offices and other sources of news distribution having to increase their staffs and work overtime to satisfy the urgent demands made upon them. Street railways did a flourishing business, taking people to and from the newspaper offices, where the bulletins were hourly displayed.

When, early in September, the country began to settle and prepare to assist in carrying the burden of the Empire obligations, the general impression seemed to be that Canada's principal duty would be to supply men for overseas service, and the response in this connection during the first six months of the war will ever remain a bright historical fact in the pages of the world's history. It is however along the lines of industrial activity, and more particularly in connection with what the metal-working branches have accomplished towards the

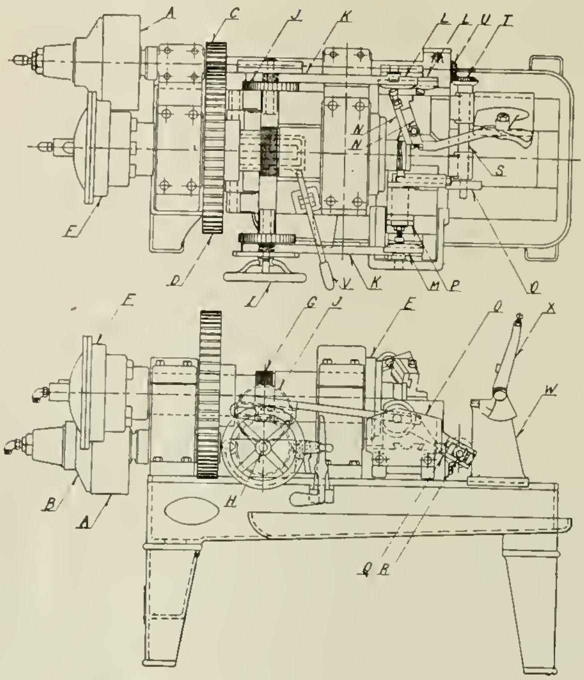
SPECIALLY BUILT AND EQUIPPED SHOP FOR MACHINING LARGE SIZE HIGH EXPLOSIVE SHELL.

successful prosecution of the war, and the achievement of our many machine shops in the manufacture of the various classes of munitions during the past three years, that this article has to deal.



INTERESTING SHELL COPPER BAND WAVE AND GROOVE MACHINE DEVELOPMENT.

Initiation of Munitions Manufacture

It was towards the close of 1914 that rumors began to circulate that the manufacture of shells in Canada was being given careful consideration, but for some time many were dubious of undertaking such a task, accomplishment of which required knowledge and experience of such a nature that few in this country were possessed of. The lack indicated failed to dampen the enthusiasm of those of our captains of industry, who had set themselves to carry out the establishment of shell-making in this country, for, after a few preliminary negotiations, the decision to manufacture was immediately followed by actual operations. It must not be supposed, however, that the foundation of the present industry was laid with the intention of erecting the massive structure that has subsequently been raised. Optimism had not yet entirely disappeared, it being still the belief of a majority that the war would be of short duration, and the need of large quantities of ammunition would be unnecessary. Therefore, when those plants that had first undertaken the production of shrapnel shell were equipping for this purpose, they did so with the belief that the first order would probably be the last, and little provision was made for future extensions or increased production. The failure to foresee the future was one of the chief factors of the early difficulties that beset many manufacturers who were previously provided with much of the equipment suitable for making shell. Regarding manufacturing methods for successful shell production (that of performing separate operations on different machines), the early utilization of existing equipment resulted in much confusion in the progressive movement of the product through the shop; but where it was possible to previously arrange the position of the various tools, this objectionable feature was largely eliminated. Some difficulty was experienced during the initial stages of the shell industry in obtaining the desired machinery, it being the prevailing opinion that standard equipment of high quality was the only kind that could be used for the purpose.

Renewal and Still Larger Orders

As time passed, the growing need for more and larger shells was impressed upon the minds of those who had inaugurated this new business line into the Dominion, and the success of the initial attempt had proven to the Shell Committee the fact that Canada was not only equal to the manufacture of munitions, but that in a large measure she was able to set the pace for greater and more efficient production. The outcome of this was the renewal of orders for shrapnel and 18-pdr. high explosive shell, and the placing of substantial orders for the larger sizes. This eventuality was probably the first intimation of the magnitude of the task that the Canadian people were called upon to perform, and from that time it might be said that a new epoch had been started in the industrial development of our country. The placing of shell orders was so general and widespread that it was practically impossible to secure equipment of a suitable character for the desired purpose, and the boom that followed in the machine tool industry has never been equalled in this or any other country. Had sufficient machinery been available to meet the enormous demands of the abnormal conditions, the probability is that the methods of manufacturing shells would have still been along the lines that were the general practice during the early days of the war.

Plant Extensions and Developments

The realization of the urgency of the Empire's needs stimulated to action many wavering plant executives, their response being exemplified in the mushroom growth of numerous new factories and additions to existing ones. A feature of early conditions, and one that reflected unfavorably upon the chief munition authorities, is the unquestionable fact that shell manufacturers were compelled to a large extent to grope about for specific information regarding officially recognized manufacturing methods, both as regards the making of shell and their parts. In the end they had to rely upon their own initiative for the design and subsequent adoption of such devices and attachments as would facilitate production. This feature, which at the time may have appeared one of the chief difficulties of the situation, has undoubtedly proven to be the essential factor in the remarkable evolution of the special purpose machine.. Too much credit cannot therefore be given Canadian manufac-

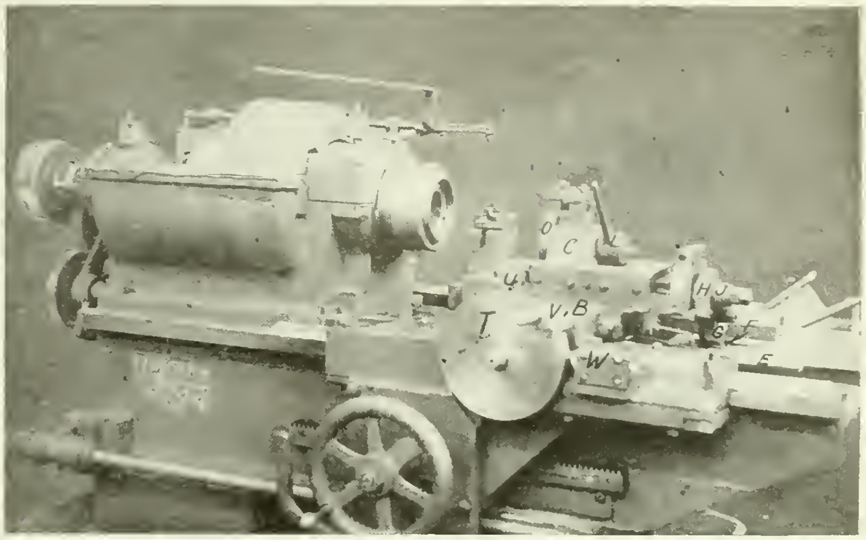
SHELL WAVING AND GROOVING FOR COPPER BANDS ON SINGLE PURPOSE LATHE WITH SPECIAL ATTACHMENT.

turers for the voluntary mobilization of their industrial resources, both physically and mentally.

Growth of the Special Purpose Machine

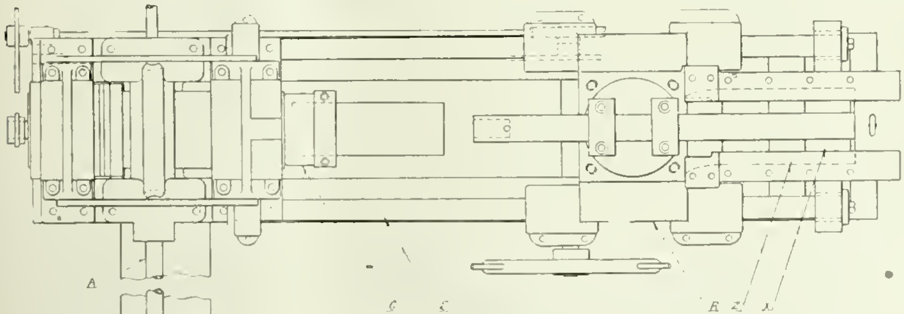
When the many firms that had contemplated the production of shell were confronted with the problem of securing equipment, and the fact that the supply was far below the demand, a temporary feeling that the task was beyond them seemed to take hold of the various executives. This depression was however, short lived, and from a condition that was next to despondency arose the spirit of determination that has been characteristic of the people of Canada during nigh three years. To meet the requirements of the situation therefore, it was necessary for each individual plant to "work out its own salvation,' with the result that the revolution in machine tool design, for the accomplishment of a specific purpose received a stimulus from which great things have been accomplished. Machines that had been relegated to the scrap pile, and others that had not even received a passing thought in connection with their being used for shell operations were given careful consideration with a view to their being utilized for some work in the routine of machining. As a result, not only were many of these discarded tools of good service, but not a few of them proved to be the nucleus from which the special or single purpose machine has been constructed.

The development of special attachments for the more rapid performance of certain operations has also been the ground work for the design and construction of special equipment for the making of shell. From these impromptu devices have been evolved many of the single purpose machines that has made it possible to manufacture munitions on a scale that would have been considered beyond all possibility at the commencement of the war. While there are at present large numbers of standard lathes



SPECIAL TURNING AND THREADING EQUIPMENT FOR 8-INCH H.E. SHELL ADAPTERS.

doing very good work in various plants throughout the country, it might be well said, and with no great stretch of imagination, that if the thing had to be done all over again, the recognized standard lathe so familiar to us all, would receive little attention in the actual machining operations of any size of



DIAGRAMMATIC REPRESENTATION OF 6-INCH SHELL BORING MACHINE.

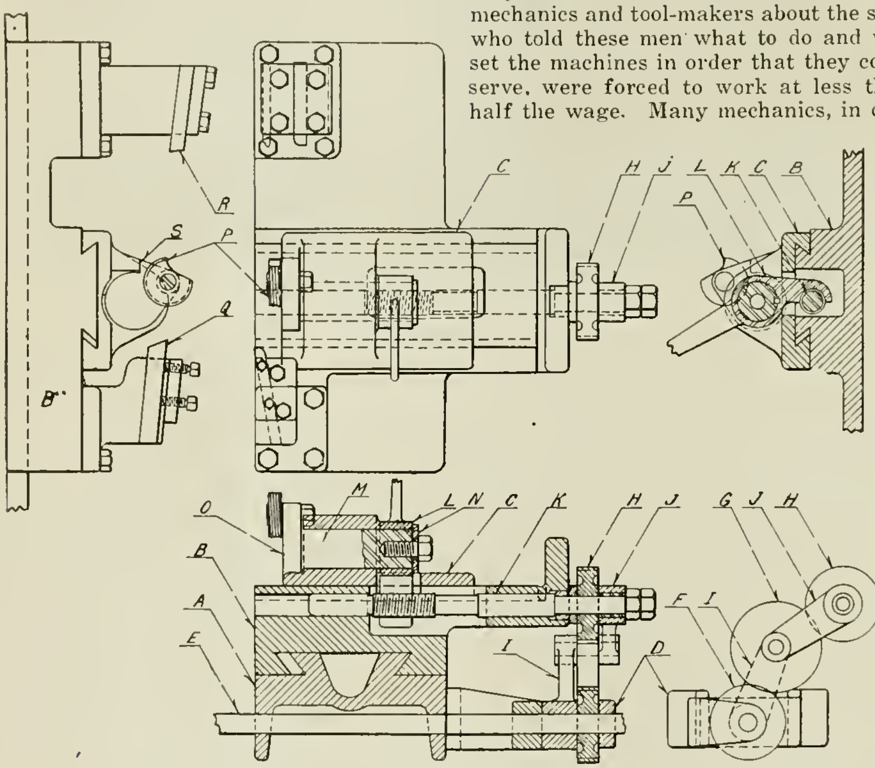
shell. As one passes through the shell plants of to-day, it is difficult to realize the changes that have taken place since the inception of this vast industry. Where the equipment appears to be the same, close observation and inquiry will reveal the fact that attachments have been added and others removed to provide increased productive powers to each and every machine. When occasion required the replacement of a certain tool it was seldom that another of the same type was installed, owing to the rapid development that has taken place both in design and efficiency.

New Order of Things—Typical Example

While visiting a plant some few weeks ago that has been making shrapnel from the very beginning of the war, there was forcibly impressed upon the writer, the changes that have taken place in this particular shop during the past two years. With practically no addition to their floor space, this firm who two years ago were working to full capacity, turning out 700 or 800 shells per day, are now producing on an average about 5000 per day; with probably one or two exceptions every machine at present in operation is of special design and constructed on the premises. While the main portions of many of these machines are practically identical, the machining attachments are designed for a specific purpose, and the machine could not very well perform another operation than that for which it has been constructed. Under existing conditions, however, this feature has no drawbacks, as each machine can be kept constantly at its own task during the entire 24 hours of the day.

Tool Making Factor

During the past three years, with the probable exception of the first few months of disorganization, everything seems to have worked out to meet the requirements of the changing conditions. Before it was definitely learned that shells were to be made in Canada, and even afterwards, many skilled workers had joined the colors and manufacturers were wondering what could be accomplished if a scarcity of mechanics should develop and they were forced to rely upon unskilled help for the production of a product that required such accuracy in its manufacture. Under ordinary conditions, these fears might have been realized, but as events transpired, the danger did not lie so much in the lack of skilled mechanics for the machining operations on shells. Where the difficulty did arise was in the inability to obtain sufficient toolmakers to provide the necessary jigs and gauges for the maintenance of maximum production. Although previous to the inception of shell-making there was a large surplus of unemployed, it eventually proved a difficult matter to secure the men required for the capacity operation of the various plants, and it was found necessary to engage any class of help, no matter what their previous experience.



SPECIAL TURNING AND THREADING EQUIPMENT FOR 8-INCH H.E. SHELL ADAPTERS.

This at first had many drawbacks, owing to the fact that many of the men engaged had never seen the inside of a machine shop before, and these had to be taught some of the fundamentals before any progress could be made. This was particularly true where such men were placed on standard lathes or other tools that had many attachments of which they knew nothing, and which were not required for the special work they were engaged in. With the introduction of the special machines, however, the possibility of getting mixed in the operation of the mechanism was largely eliminated, and from that time it mattered little whether a new man was a mechanic, baker, barber or bootblack, as he soon became skilled in the performance of his particular duties. As a matter of fact, it was often found that men of this description could be relied upon to do more effective work than mechanics who had been accustomed to perform their work in the variety form; the repetition style of single operation to these latter being too monotonous for effective accomplishment.

Effect of High Wages

One of the factors that threatened to disrupt the operation of many plants was the scale of wages incidental to the production of munitions for which exorbitant prices were being paid; not that these were excessive under the circumstances, but so in comparison with what had been recognized as reasonable wages before the war. Here were men drafted from all departments of labor without any previous experience in machine shop practice, who after a few days of preliminary training were receiving three, four and even five times what they had ever earned before, while the mechanics and tool-makers about the shop who told these men what to do and who set the machines in order that they could serve, were forced to work at less than half the wage. Many mechanics, in consequence, forsook their relatively easy positions in the tool room to seek work on shell machinery where the remuneration was considerably greater. To retain the services of their tool-makers, many firms found it necessary to substantially increase the pay of mechanics in their employ, thus adding to the expense of operation, which during the first year of the war was none too light, owing to the many difficulties relative to specification requirements, and experiments incidental to the establishment of an entirely new industry.

After the War—What?

The question has often been asked as to what conditions will be after the war? It is very doubtful if anyone could, with any degree ofaccuracy, give a true answer to this question, but from the developments and experiences of the past three years it is probably safe to draw a few conclusions in the nature of a prediction as to some of the changes that may arise out of the meantime activities of the industrial world and the altered conditions that will prevail when peace is declared. Had the war been of short duration, it is reasonably fair to assert that we would have again returned to the old condition where the great majority of the people of the so-called civilized world were undoubtedly (and probably unconsciously) relying on Germany for certain classes of brains and material. The experience now so forcibly pressed upon us will not, however, permit of us again placing ourselves at the industrial, commercial or intellectual mercy of such a country as Germany, or in fact any other.

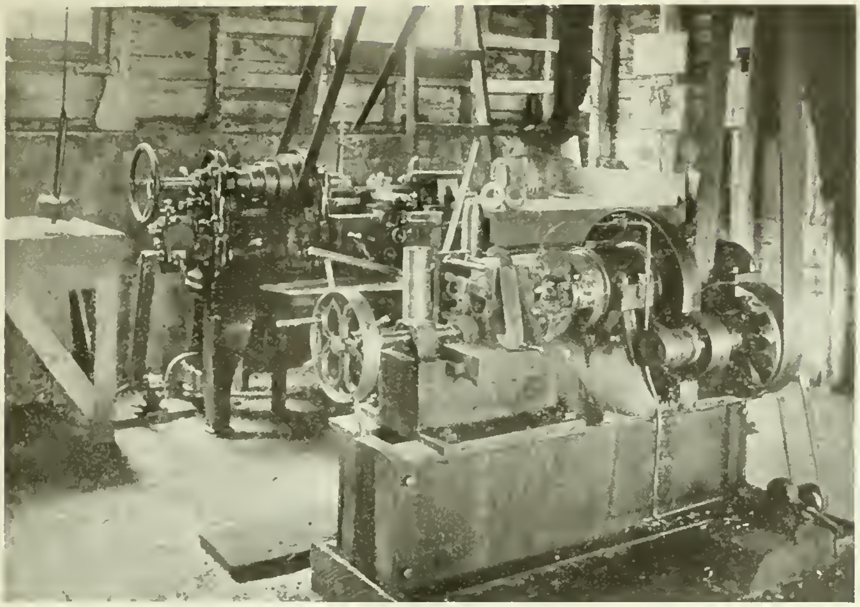
The revolutionary manufacturing methods of the war years that have just passed will make it almost impossible for things to follow along the same course as that preceding the war. Industrial developments, both scientific and practical, have been of such a character that future commercial activities will be conducted with a wider and more expert knowledge than ever in the past. The rapid and efficient progress in the manufacture of steel and the extensive experiments that have been carried out will place this industry in a much superior position, and will form a basis for stil lfurther developments in this and kindred industries.

Machine Shop Practice on New Basis

Out of the manufacture of shells will evolve a new practice in connection with machine shop development. The methods that have proved so successful in the production of munitions on such a vast scale will naturally have considerable bearing upon the future practice of plants manufacturing in large quantities. The standard type of machine will not likely be superseded by any other, but where it is possible to manufacture articles of a special nature, using the principle of the single purpose machine for separate operations, production methods will undoubtedly undergo many changes. It is generally supposed that many of the machines now engaged in the making of shells will be fit for nothing but scrap after they have served their purpose; still there will also be a great number of those special machines that will find a useful place in the work of many plants.

Copper and Brass Products

Not only has the shell activity enlarged our steel outlook for the future, but the component parts, such as copper bands and cartridge cases, have developed an industry that will undoubtedly mean much to Canada when the post-war readjustments are being made. The copner and brass requirements for the manufacture of cartridge cases and the parts in connection with the various shells have grown to such proportions that the production of these has become equally important with that of the shell bodies. Plants now established in the Dominion for the manufacture of copper products, while primarily operated in the interests of munitions, will likely take a leading position in domestic activities after the war. In many respects, the tools now engaged in the production of shell may be of little use for any other purpose, but



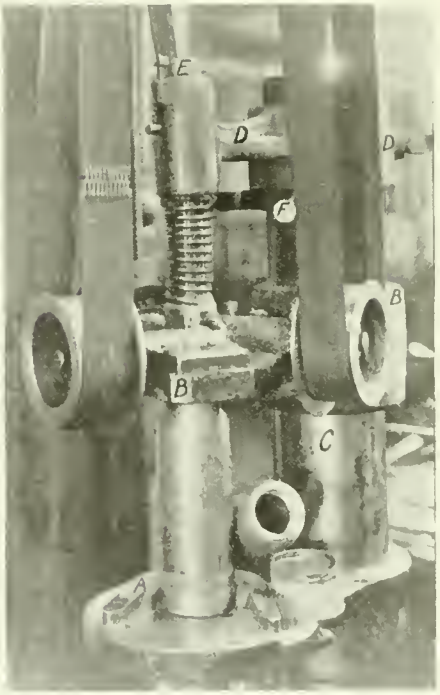
ROUGH NOSING AND PROFILING H. E. SHELL.

the machinery now used for the manufacture of brass discs and also cases will be in comparatively good condition and fit for a wide range of commercial work. The essential feature, however, will be to find sufficient work of a suitable nature to keep the large number of presses now used on cartridge cases engaged in normal times.

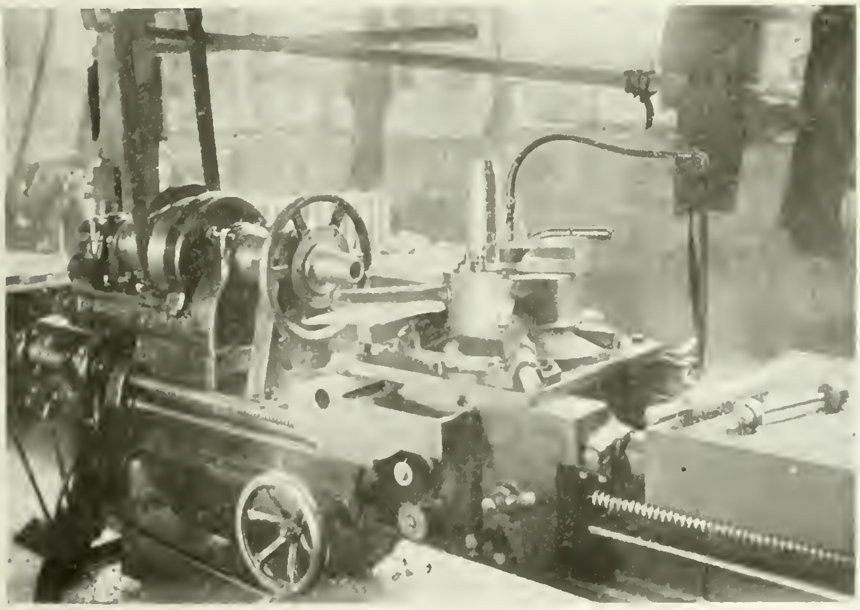
The time is not yet opportune to predict the actual use to which the bulk of this equipment will be put, but with what has been learned during the past few years regarding more efficient forging and drawing of copper, brass, and steel material, it may be expected that many revolutionary methods will take place in the manufacture of small parts that have formerly been made in other ways. This seems to open opportunities for the replacing of many small cast parts by similar pieces manufactured from sheet stock and pressed into the desired shape, giving greater strength with lighter material.

Post-War Status of the Mechanic

The status of the mechanic will be one of the most serious problems after shell-making activities have been concluded. With a short war and a similar acquaintance with the operation of mechanical equipment, the possibilities of a ready return to their previous calling was more than likely, but large numbers of men and boys have virtually served an "apprenticeship," or a period of time equalling that served by the average mechanic of to-day, and it is more than probable, in fact, a certainty, that large numbers of these shell "mechanics" will desire to continue in this line of work. If certain manufacturing methods are adjusted to suit the revolutionary changes that have taken place, the situation may be relieved of much of the pressure that would otherwise be evident. Men, who before the war, were content to work for comparatively small wages, may not be satisfied to again do so if they think they can hold a position in a machine shop where the remuneration will be almost double what they would receive at their old work. Many of these men, three years ago, did not know the difference between an eighth of an inch and a thirty-second, and many of those who did were not required to work closer than the former measurement. Their knowledge of these matters has undergone radical change, and in place of sawing a board to a line that is one-eighth of an inch wide, or cutting hair for appearance, these men are actually working to a thousandth of an inch, and have also become very apt in the manipulation of the various tools and gauges. The fact that female labor has been largely and successfully requisitioned for shell making constitutes an addition to the problem of the mechanics post-war status.



NICKING SHELL NOSES.



INSIDE SHELL FINISHING EQUIPMENT.

Shipbuilding

From the earliest days of the war, the question of ocean tonnage has been an ever-present and pressing problem, developing in acuteness since the submarine became a contending factor in the destruction of life and property. It is unnecessary to emphasize the importance of this particular phase of modern warfare and its possible effect upon the commerce and general well-being of all nations, it being enough to say that the wastage must be replaced as rapidly as possible in order to prevent serious consequences in the matter of the food supply of various countries. How this objective is to be achieved is the question of the hour, and one also that will continue with us even after the war has terminated; in fact it may be more pronounced at that time than it is at present. As a companion activity to that of the manufacture of shell, and one that will become an essential industry for many years after the war, it would be well for Canadian manufacturers to give this matter equal consideration with that of munitions with a view of placing it on the same successful basis as that at present maintained by the latter industry. While the nature of this new obligation may not permit of the same tactics in establishing a Dominion-wide industry, it might be well to consider the possibility of nationalizing the undertaking so that the entire operations may be controlled and developed along the lines of the past three years of munitions manufacture. The difficulties that surround the actual construction of the hull and its component parts make it evident that this can only be successfully accomplished close to a permanent waterway, and by a properly constituted shipbuilding plant. In the case of internal equipment of almost every description, however, there seems to be no good reason why production could not be undertaken somewhat on the lines of shell manufacture. With the cessation of hostilities, thousands of machine tools will be idle all over the country, and with a little forethought it might be possible to utilize a large portion of these in furthering the speedy progress of vessel equipment, so that the shipyards could concentrate all their efforts on the fabrication of the main structure.

Opportunities and Responsibilities

Apart from the ravages of war, there appears to have opened up for this country possibilities that could never have taken place under any other conditions; closer co-operation between master and man, and also between the captains of industry and their various executives; intercourse between the numerous industrial plants in all parts of the country; all classes of workmen, draughtsman, tool-makers, machinists and even unskilled workers, have had to do and think things which otherwise would never have happened. The vast acquisition of additional knowledge concerning the foundry, machine, and chemical sciences, has opened the way for very material advancement, and the time appears to be ripe for Canada to pluck some of the fruits of the past three years; fruits that have matured through the perseverance of men who have sacrificed much for the greatness of Canada's future. All that is needed is capable pilots to guide the course of the new industrial ship of progress, avoiding the narrow channels of industrial strife and the sunken rocks of political prejudice.

Lest we forget, however, it might be well to call attention to the fact that eventually Canada must again receive to herself the human remnants of a devastating war, men that will return physically unfit for the duties they were accustomed to perform before the war. What the country owes to these men, God only knows, but it would be a sad day for this country, and more especially those interests that have reaped financial prosperity through the personal sacrifice of these very men, if some means were not provided for their permanent welfare on their return home. Steps should be taken by the various industrial heads in co-operation with the Government to establish some form of national manufacturing industry that would provide employment of a suitable character to men unable to compete in an open market. We, as a nation, are in duty bound, to provide for these men who have made it possible for our progress of the past; and our future cannot be darkened by the posibility that any of these men will regret the part they have taken in shielding this land of ours from the ravages of the murderous Hun.

It is unnatural to expect that individually controlled plants, in competition with others, will give this question the consideration it deserves; not that each would he unwilling to share the burden, but as the effects of the war become less pronounced, there arises the possibility that their recognized responsibilities may not seem so great as formerly, with the result that the country would be over-run with maimed men discharged because they were unfit to perform the duties required. Under a system controlled by the government, and aided by the manufacturers in common, this contingency could be avoided, as where a man was found unfit for certain employment, other work of a suitable character could be found and, if not, it would be the duty of the Government to provide for him the same as for any other; the essential factor being that he *be* amply provided for. Let it be demonstrated that the industrial aspirations of the post-war period are not to be attained without first considering those to whom so much is due.

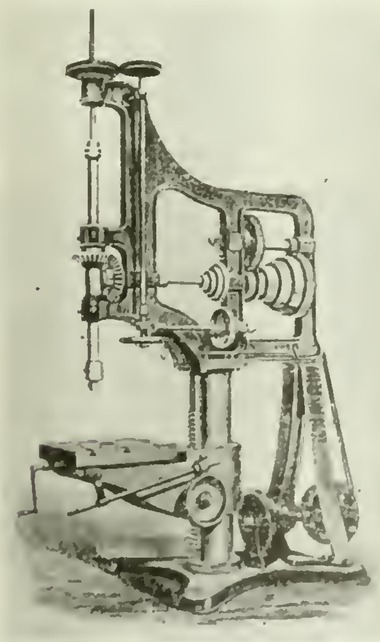
SHELL BASE RECESSING EQUIPMENT.

Canada's Machine Tool Industry in Retrospect

By the Editor

It will be readily gathered from the article text and illustrations that Canada's machine tool manufacturing achievement is no mean one, rather must it be reckoned as one of her prominent national assets. That its future development will be much more rapid than it has been in the past, goes without saying, for not only do we now have a substantial base of operations to branch out from, which the early pioneers had not, but we have through participating in munitions manufacture realized the possession of a competence in things mechanical that was either previously considered non-existent, or at best non-vital.

THE initiation of machine tool manufacture in Canada according to records available antedated Confederation by something like twenty three years. Strictly speaking, of course, the actual production of what later became known as machine tools did not then really commence, the establishment of business enterprise to that end was, however, successfully accomplished. It is worthy of note at this juncture that the chief centres of Canada's machine tool industry to-day, both wood and iron working, are still to be found in the locations of its inception—Galt and Dundas, Ont., notwithstanding the fact that the exigencies of the munitions situation during the past two years or more had the effect of adding materially to the number and territorial distribution of Canadian machine tool manufacturers in order to meet the very abnormal requirements of our shell forging, shell machining, and shell loading plants. More of this latter phase of the situation anon.



VERTICAL DRILL BUILT ABOUT THE YEAR 1869

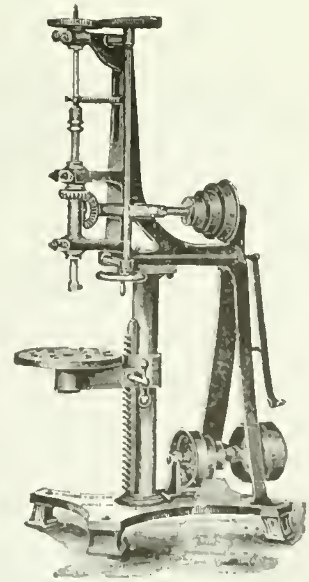
This article was prepared for and is here reproduced from the Toronto "Mail and Empire" Special Confederation Number.

As might be expected, away back around the year 1844, settlers—for the the most part, if not wholly from the Old Country, directed their efforts, whether for an existence or a competence, to agricultural and lumbering pursuits; the latter being at one and the same time a necessity so as to provide the construction materials for a shelter and a home, and for the clearing of the land for purposes of cultivation. It is somewhat significant that the men who had braved the perils of the Atlantic, and had endured the discomforts of the then long voyage across its angry bosom on none-too-well-found ocean transports, were not in every case "sons of the soil" in their native land. Some of course could lay claim to such a title, others had been engaged in pursuits somewhat akin, while others again, were tradesmen—mechanics if you will, because more correct—nimble with hand tools, keen of perception, and brimful of ideas. Sterling integrity was, however, a marked feature in all, which taken together with nature-endowed aptitude for surmounting difficulties, enables it to be truly said of the result of their activities that "their works do follow them."

Galt, Ontario, so far as we can gather, has rightful claim to be given attention first in matters concerning the inauguration of machine tool building in Canada, for there we find that James Crombie established a foundry in the year 1844, twenty-three years previous to Confederation. In 1847, Dean Fisher and Morris C. Lutz began a partnership in Galt as manufacturers of agricultural machinery and, as indicative of the like desire as now exists all over Canada to foster the establishment and location of industries, we find one James Dickson, owner of the township lands, leasing same at reasonable rentals, bonusing manufacturers, leasing water-powers for ever at a nominal annual rental, and building the dams accessory to the latter, etc.

Goldie & McCulloch Co., Galt, Ont.

In the year 1849, John Goldie and Hugh McCulloch, both a number of years deceased, entered into partnership and purchased from the already-mentioned James Crombie, his foundry established five years previously, and known as the Dumfries Foundry. These two Scots,



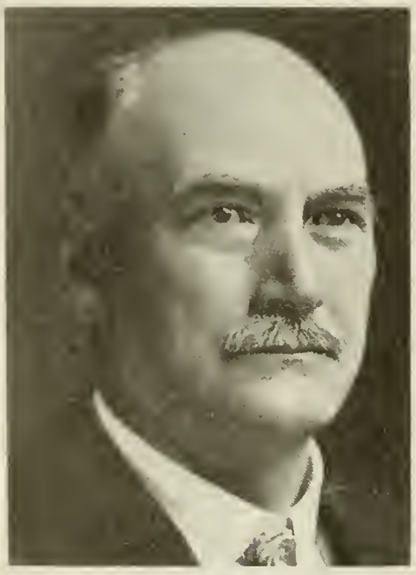
DRILL BUILT AT DUNDAS IN 1865.

then in the prime of manhood had, in so doing a taste for the first time of the responsibilities attaching to the management and administration of a manufacturing business. Relative to the enterprise they demonstrated, it has been given us to understand that their working capital consisted chiefly of high purpose, pluck and energy, all of which qualities, as might be expected, have had their reward in the intervening years, and in the honored place which the Goldie & McCulloch Co. of Galt, Ontario, now fills in Canada's general mechanical and steam engineering activities. The plant taken over from James Crombie was quite small, the pay-roll, as a criterion, embracing only some twenty-two persons. To-day, the employees number over five hundred, which, taken in conjunction with the substantial nature and extent of what are known as the North and the South Works of the firm, gives abundant evidence of rapid yet steady growth through a period of sixty-eight years.

Originally the firm engaged in what was known then as a general foundry business, same including the manufacture of boilers, engines, and mill machinery. Woollen mill machinery and the manufacture of machine tools for woodworking services were added as opportunity offered and necessity demanded, with the result that in the latter feature something akin to pioneer effort had been successfully undertaken and a reputation established. In the course of time, around the year 1880, the Goldie & McCulloch Co., gradually withdrew from the manufacture of woodworking machine tools and general machinery, having decided to specialize in the production of fire and burglar proof safes and vaults, stationary steam boilers and engines, the latter more especially of the simple slide valve and corliss type.

In more recent years, they have devoted attention to the manufacture of Wheelock, Goldie-Corliss, Ideal horizontal high speed, and vertical high speed engines, steam turbines, water-tube boilers, heaters, pumps, condensers, return tubular boilers, transmission and elevating machinery, safes, vaults, vault doors, etc. The North Works built about twelve years ago embraces a shop 480 ft. long by 120 ft. wide, constituting one of the largest of its kind in Canada. In these war times, not a little of the firm's activities comprise the forging and machining of shrapnel shell, as well as the building of marine engines.

THE LATE JAMES COWAN, A PIONEER IN WOODWORKING MACHINE TOOL BUILDING.



HENRY BERTRAM,

Son of John Bertram.

Cowan & Co., of Galt, Ltd.

Getting back to the partnership of Fisher & Lutz, we find that the former retired in the early "fifties," his place as an active member of the firm being taken by Peter Cook, and the enterprise strengthened as a whole by the assumption of James Cowan as a silent partner; the undertaking was now known as Lutz, Cook & Co. Stoves, plows, and threshing machines were the particular lines manufactured. It is of interest to note here that the James Cowan above-mentioned was father and grandfather, as the case may be, to the men who to-day are the executive officers of the well-known firm of woodworking machine tool builders, Cowan & Co. of Galt, Ltd. In 1859, Peter Cook, partner, was accidentally killed while at work in the plant, his death causing the firm name to be changed to Lutz & Co. Thomas Cowan, son of James Cowan, entered the firm at this time in an active capacity. Reapers, mowers and agricultural machinery of a variety nature were next added to the already noted lines of manufacture.

In the early "seventies" Lutz & Co. sold out to Cameron & Co., the latter firm consisting of J. Cameron, J. Ballantine and J. Smith—woodworking machine tool mechanics from the plant of Goldie & McCulloch—and Thomas and James Cowan, of the defunct Lutz & Co. The silent partnership of James Cowan was maintained unbroken, we might say, all the way from his association with Lutz, Cook & Co., until his death in 1897. The manufacture of engines, boilers and woodworking machinery occupied the attention of Cameron & Co to a large extent. Smith and Ballantine severed their connection with the company within a year or so, and at a later date when Cameron expressed a wish to retire, James Cowan bought his interest, the firm name becoming thereafter Cowan & Co. In 1902 incorporation as Cowan & Co., of Galt, Ltd., was procured. Since 1905, the manufacture of engines, boilers and miscellaneous machinery has been entirely discontinued, the whole effort and energy—administrative and operative—being concentrated on the production of high-grade woodworking machine tools of all types, and for special or general service requirements.

Of human interest is the fact that James Cowan was a shepherd in the lowlands of Scotland before coming to Canada in 1834. Further, his trip from his native to his adopted country constituted his honeymoon. That Galt has grown in the period under review may be gathered from the statement that, when Mr. Cowan and his bride claimed its hospitality, there were but fourteen houses within its borders. Mr. Cowan was member for South Waterloo in two parliaments—Upper and Lower Canada period, and was in the House when Confederation was put through. For a number of years he held the appointment of Federal Government arbitrator over the territory extending from Halifax, N.S., to Winnipeg, Man., his special duties being the adjustment and settlement of claims in which railroads, public works, lands, and individual interests were involved.

Arising out of Canada's munitions industry of the past two and a half years, and particularly in relation to the shell shipping box feature, a series of special boring machines were designed and built, the spindle capacities of which were capable of producing 1-2-4-5-12 and 18 screw holes at one operation. Other special shell box machinery designed was

BRIG.-GEN. SIR ALEXANDER BERTRAM.

Son of John Bertram.

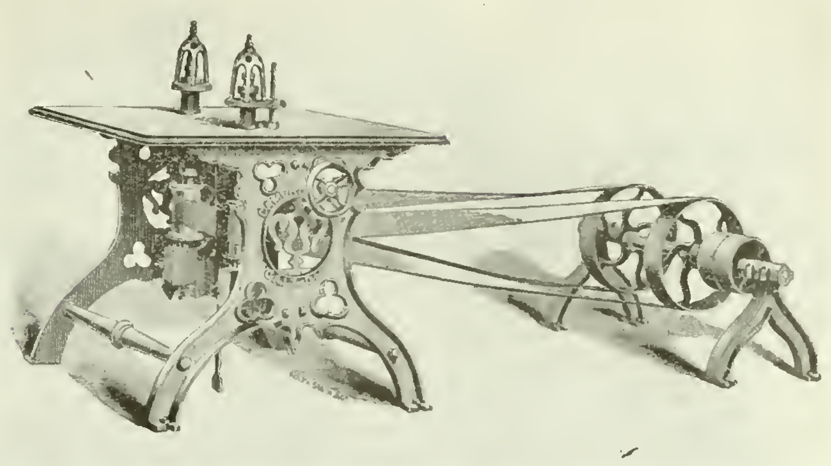
that relating to the rapid and efficient fitting of the box parts, as well as to the ease and convenience with which the latter could be taken asunder when shell were being extracted in the field.

The executive of Cowan & Co., of Galt, Ltd., at the present time consists of William Cowan, president; A. B. Cowan, vice-president; James H. Cowan, secretary-treasurer; J. L. Cowan, and J. Roy Cowan, directors. About 90 men are meantime employed, although the work on hand and in prospect is such as to warrant half as many more being on the payroll, were they available.

Canada Machinery Corporation

The establishment of what is now known as the Canada Machinery Corporation took place in 1872, some five years after Confederation had been accomplished. The original enterprise was known as Cant, Gourlay & Co., the individual members all of whom were practical mechanics, being Adam Cant, John Ross, John Gourlay, and William Laidlaw. In 1876 the personnel of the concern underwent a change, John Ross and William Laidlaw withdrawing from the partnership. The present site of the plant was built upon during the same year, the previous location occupied being on Water Street North.

In 1881, on the death of Adam Cant, R. MacGregor assumed the latter's interest, and A. G. Gourlay joined the firm. With the retiral of John Gourlay in 1886, R. MacGregor and A. G. Gourlay took over the business, the firm name being changed forthwith to that of MacGregor, Gourlay & Co. The latter was incorporated in 1895 as MacGregor, Gourlay & Co., Ltd., and continued as such until 1910, when the Canada Machinery Corporation was formed. The present officers are:—T. H. Watson, of Toronto, president; B. H. Neill, secretary-treasurer; W. Baird, sales manager, and R. M. Hamilton, general manager. The head office and parent plant are located in Galt, adjacent to the Grand Trunk Railway Depot. There, a complete line of light woodworking, as well as general metal-working machine tools, are designed and built, the range and variety type covering such exacting requirements as those of railroad locomotive and car-building shops, pattern, boiler, and machine shops, specializing or otherwise. Branch plants in operation at Preston and Hespeler, towns adjacent to Galt, are actively employed supplementing the headquarters output.

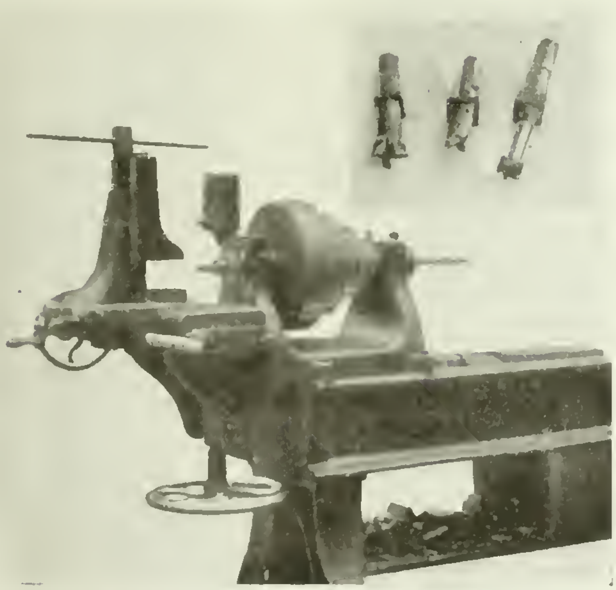


UPRIGHT SHAPING MACHINE OF EARLY CONFEDERATION PERIOD.

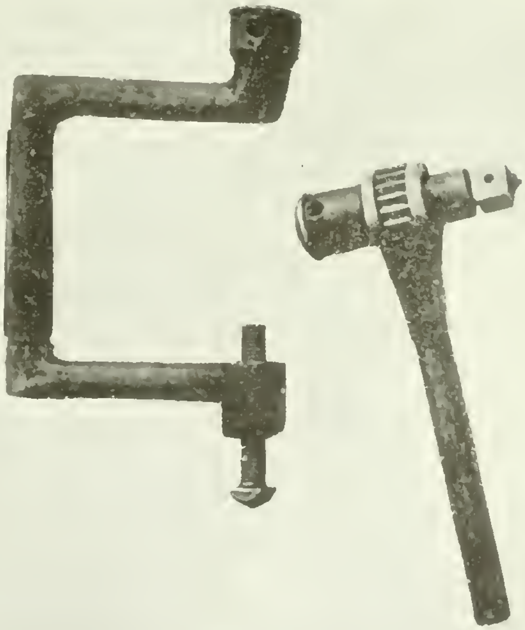
When first established, woodworking machine tools only were manufactured but with the advent of R. M. Hamilton in 1895 from the Stevens, Hamilton Co., which the MacGregor, Gourlay Co. bought out in that year, attention was given to the production of machine tools for metal-working services. Since then the two departments have gone hand-in-hand, advances made in either one appearing to pave the way for a forward step in the other, to the mutual benefit of each and the enhancement of the C. M. C. reputation. In 1911, the London Machine Tool Co. of Hamilton, Ont., was absorbed by the Canada Machinery Corporation, the activities of the Hamilton plant being transferred soon after to Galt, by removal of the equipment there, and the land and buildings in Hamilton, being sold.

R. McDougall Company

The business of the R. McDougall Co., Galt, Ont., builders of metal-working lathes, shapers, drills, pipe machines, and well pumps of a variety type and size, was established by R. Middlemass in the year 1877, ten years after Confederation, windmills, with their accessory pumps, being the particular lines undertaken. R. McDougall, who still takes an active part in the production activities of the plant which has for many years borne his name, became associated with the enterprise some two years later. From 1879 to 1895 attention was pretty well divided between the manufacture of the Claxton hot water boiler, the already-mentioned windmills with their accessory

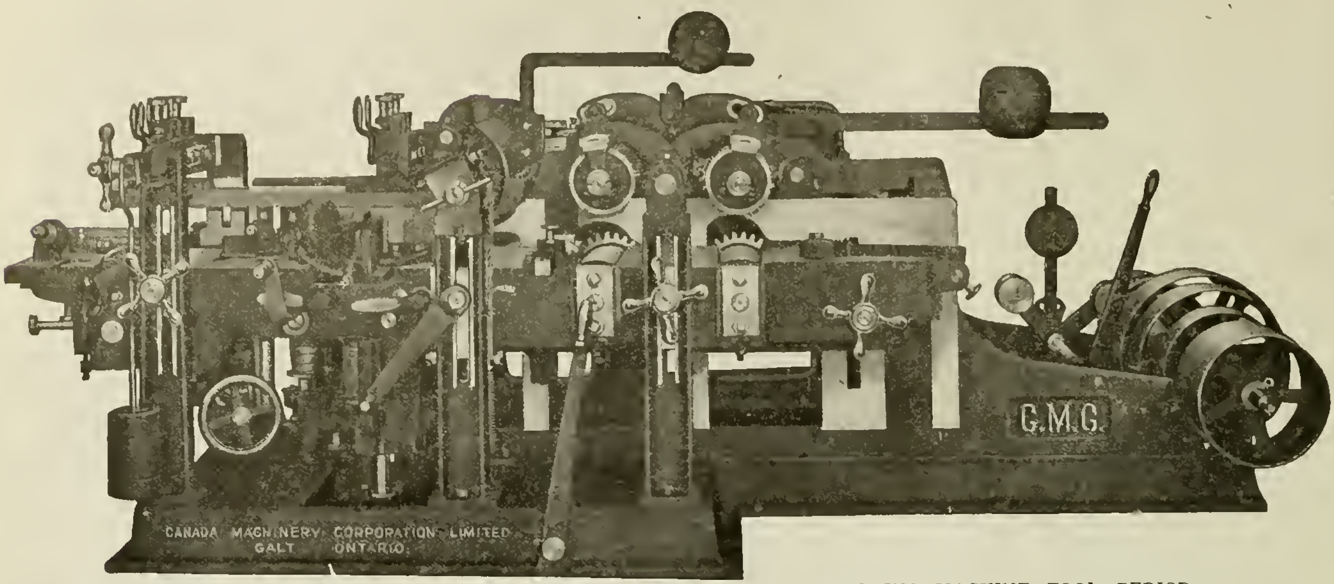


MILLING MACHINE FOR CUTTING KEYSEATS IN SHAFTS, BUILT A FEW YEARS PREVIOUS TO CONFEDERATION



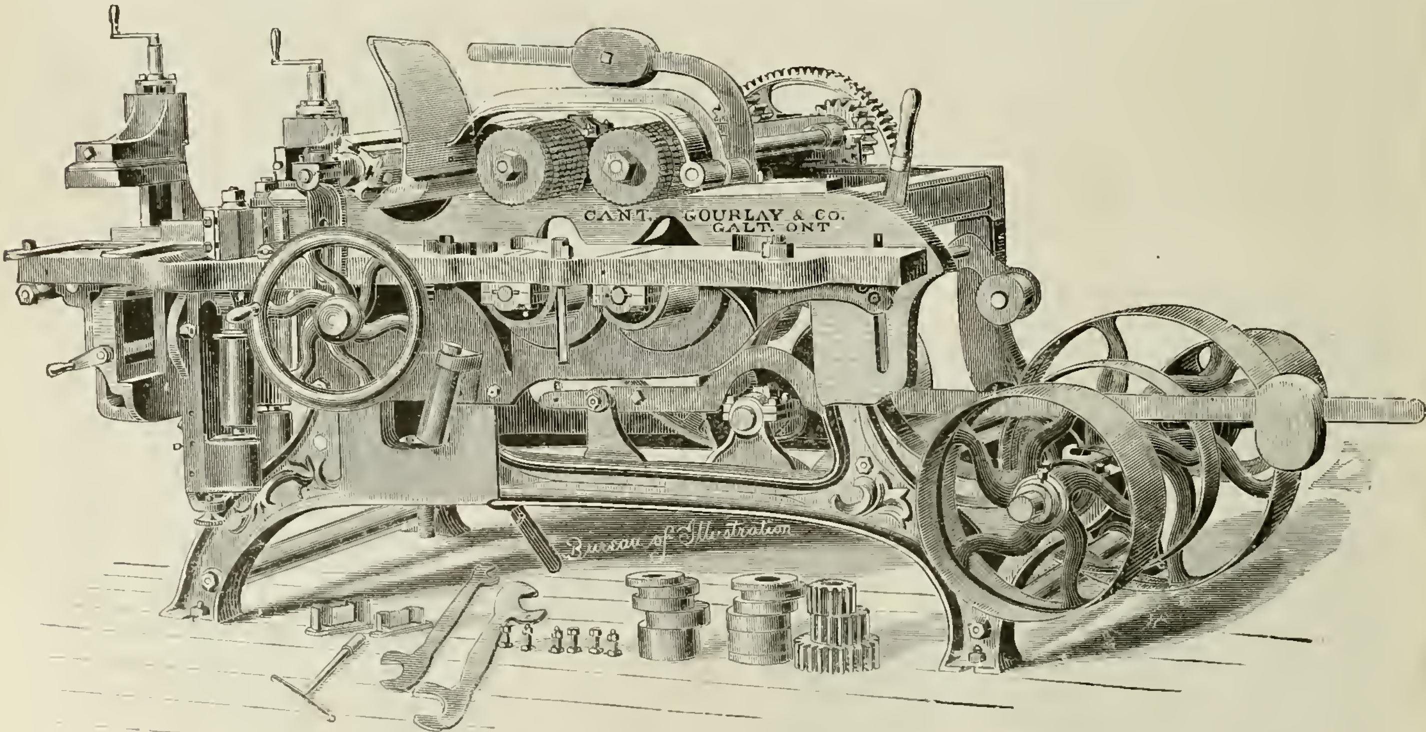
RATCHET AND BRACE IN SERVICE 46 YEARS AGO.

pumps, and well pumps for hand operation. In the latter year, however, the production of metal-working machine tools was commenced, and in the interval which has elapsed success has crowned



MODERN TYPE MOULDER—COMPARE WITH THAT OF EARLY WOODWORKING MACHINE TOOL PERIOD.

the departure then made. The line of engine lathes manufactured embraces from 16 in. to 26 in.; gap lathes, 26 in. to 48 in.; and shapers from 16 in. to 24 in. About 130 men are regularly employed. As in the case of all other machine tool builders, the McDougall plant has during the past two and a half years been pushed to the limit of its capacity to meet the munitions machining requirements.



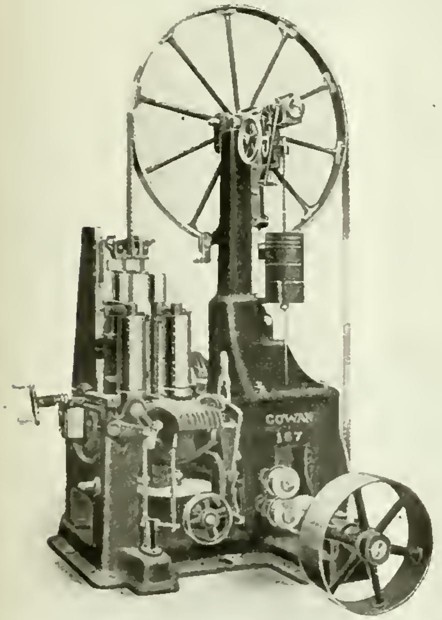
MOULDER EARLY WOODWORKING MACHINE TOOL PERIOD.

John Bertram & Sons Co., Dundas, Ont.

From what has preceded, it will be clearly evident that the initiation of Canada's machine tool industry, in so far as Galt, Ont., is concerned, was evolutionary. In Dundas, Ont., it was otherwise, for there the manufacture of wood and metal-working machine tools started off when the partnership between John Bertram and Robert McKechnie was formed in 1861. A small jobbing shop established by the latter had commenced operations a few monhs previously. McKechnie was a young patternmaker who had graduated from the Dundas foundry of the John Gartshore Co., and who had struck out for himself in a small way to carve a career in the then growing Province of Ontario.

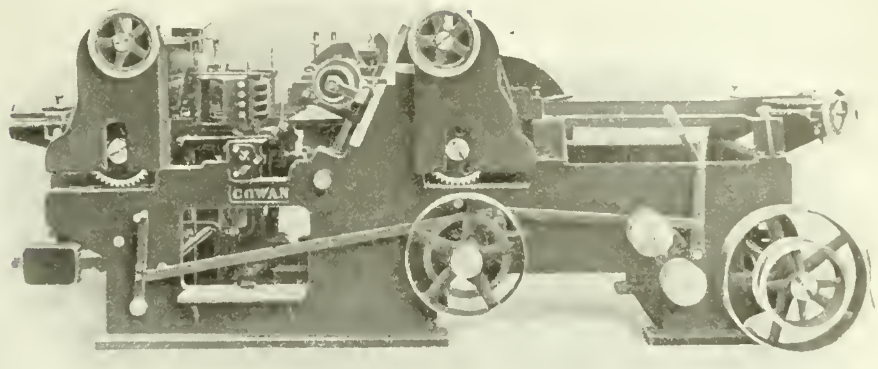
John Bertram was born in Eldelston, Scotland, in the year 1829. His early education completed, he became apprentice millwright to his uncle, Thomas Aimers, manufacturer of engine and mill machinery, in Galashiels. Having completed his apprenticeship, matrimony next engaged his attention. Miss Elizabeth Bennett, of Innerleithen, as a result became Mrs. John Bertram, and very soon after, in the year 1852, both set sail for Canada aboard the Allan Line vessel Clutha, arriving in due course at Montreal, from which they continued their journey to Toronto. When in Toronto, Mr. Bertram was advised to sail on up to Dundas by way of the then new Desjardin Canal, which he did. A noteworthy circumstance relative to the foregoing is that the whole journey from Edinburgh, Scotland, to Dundas, Ont., was made by water. Having settled on terra firma again, he took a position in the shops of the Gartshore Co., who were then probably the largest manufacturers of marine engines and boilers in Western Ontario, many of their products being installed in steamers plying on the old Desjardin Canal. Among others of the large undertakings carried out by the Gartshore Co. may be mentioned the Hamilton, Ont., waterworks, which are still in existence.

John Bertram, besides being well educated, was a skilled craftsman, and was possessed of an inventive turn of mind. as the following incident will serve to demonstrate. While employed in the Gartshore foundry, he operated a New Haven lathe which was equipped with a chain feed. This chain ran the full length of the bed, and was not accurate for thread cutting. From this lathe he designed another, but equipped with a rod and screw feed, his effort achieving what was probably the first lathe of its type to be built either in Canada or the United States, for the reason that the New Haven machines were up-to-date and most modern in style. The first of the Bertram designed lathes built had a 12-in. swing and a 6-ft. bed, and was taken when completed to the Hamilton Exhibition, held at that time in the old Crystal Palace. It was the only machine of its type exhibited, and of course took first prize. McQuiston & Co., who had a machine shop near the Royal Hotel, Hamilton, bought this exhibition lathe.



MODERN TYPE BAND RESAW, CAPACITY ¼ IN. TO 6 IN. HORIZONTALLY, AND 26 IN. VERTICALLY.

In 1865, two years preceding Confederation, the Canada Tool Works, by which name the plant of McKechnie & Bertram was known, consisted of a small frame building 24 ft. by 40 ft. A few years later this structure was accidentally burned down, and in its place there was immediately erected a rough cast building measuring 60 ft. long by 40 ft. wide. Continuing from this building, a brick structure, two storeys high and extending to Hatt Street, was erected in 1866. Eventually an addition of two storeys high was erected along the Hatt Street front; later a moulding shop was built in the rear and, as business continued to increase, another two-storey building was put up, extending from the front on Hatt Street and enclosing an area of 80 ft. by 111 ft. The firm title of McKechnie & Bertram was continued until 1886, when the partnership was dissolved. Since then the works have been operated under the firm name of the John Bertram & Sons Co., Ltd.



MODERN TYPE PLANER AND MATCHER.

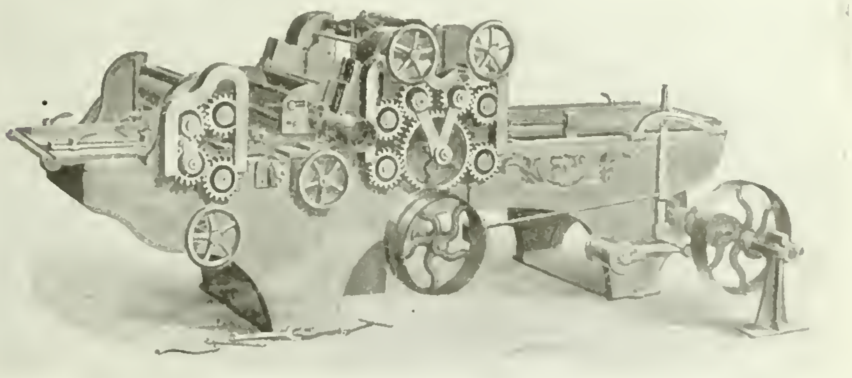
The difficulties under which the first Bertram lathe was built were increased because of the fact that similar shops to that of McKechnie & Bertram were like it, small, and were not possessed of the necessary equipment with which to plane the bed. A way out was found, however, at the Gartshore foundry, in which plant the lead screw was also cut. The planer in use there was built in Scotland and, of course, had a table of sufficient length to plane the lathe bed without a shift. It took about six months to finish the lathe, which, by the way, weighed about 600 lbs. when complete. Much of the turning of the smaller parts was done by hand tools, as there were few self-acting lathes available, and certainly none were to be found in the Canada Tool Works. All the gears—change gears included for screw cutting—were cast from wood patterns, and all the castings entering into the construction of the lathe were made at the Gurney Foundry in Hamilton. From the modest beginning indicated, McKechnie & Bertram were encouraged to greater business development effort; others, also realizing that there was opportunity offering, embarked in the same line with more or less success.

McKechnie & Bertram Planers

Following their initial achievement in lathe building, McKechnie & Bertram essayed the design and construction of planers and drills. Construction of planers was, however, beset with more or less difficulty, for the time being at least, as recourse had to be taken to the planer at the Gartshore foundry in order to have the necessary machining done. This planer, to which reference has already been made, had a 12-ft. table, and measured 3 ft. between the housings. Driving was accomplished by means of a screw. The table was so twisted, however, that the beds of the McK. & B. planer products being machined, had to be afterwards both filed and scraped. Before tracing the development of the machine tool industry—more particularly that phase of it dealing with operations on iron, steel, and metals, for, due to the rapid and steady demand for equipment of that nature, woodworking machine tool building was wholly discontinued at an early date, and the activities of the firm confined entirely to the other—it seems in order to make not only further reference to the principals of the Canada Tool Works, but also to the later activities of some of its employees.

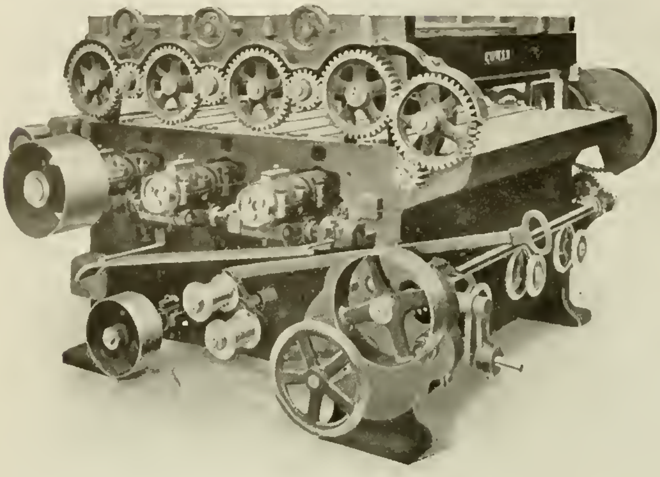
Dundas Personalities

At about the same time as metal planer

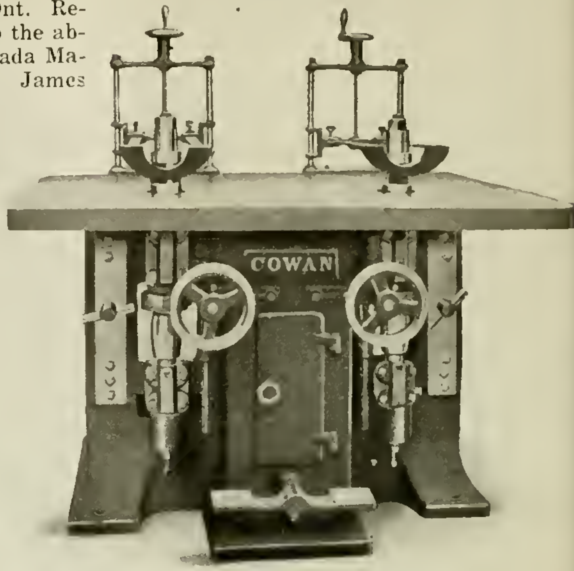


PLANER AND MATCHER OF EARLY CONFEDERATION PERIOD.

production was undertaken by McKechnie & Bertram, a shop-mate of John Bertram, by the name of William Gibson, undertook the manufacture of iron tools and set up business for himself in Dundas. From the use of the expression—shop-mate, it will be quite evident that the machine shop proprietors of those early days took their place at the bench, at the machine, or on the erecting floor along with the regular payroll employees. Gibson completed a planing machine, but his Dundas venture was not, generally speaking, a success. From Dundas he moved to Oshawa, and later to Mitchell, Ont., his brother going into partnership with him there, the result of which was the laying of the foundation of what afterwards was known as the London Machine Tool Co., of Hamilton, Ont. Reference has already been made to the absorption of the latter by the Canada Machinery Corporation of Galt. James Littler and John Maw, also employees of the firm, started out for themselves and achieved considerable success for a number of years; they, however, finally sold out, and took up other lines of effort.



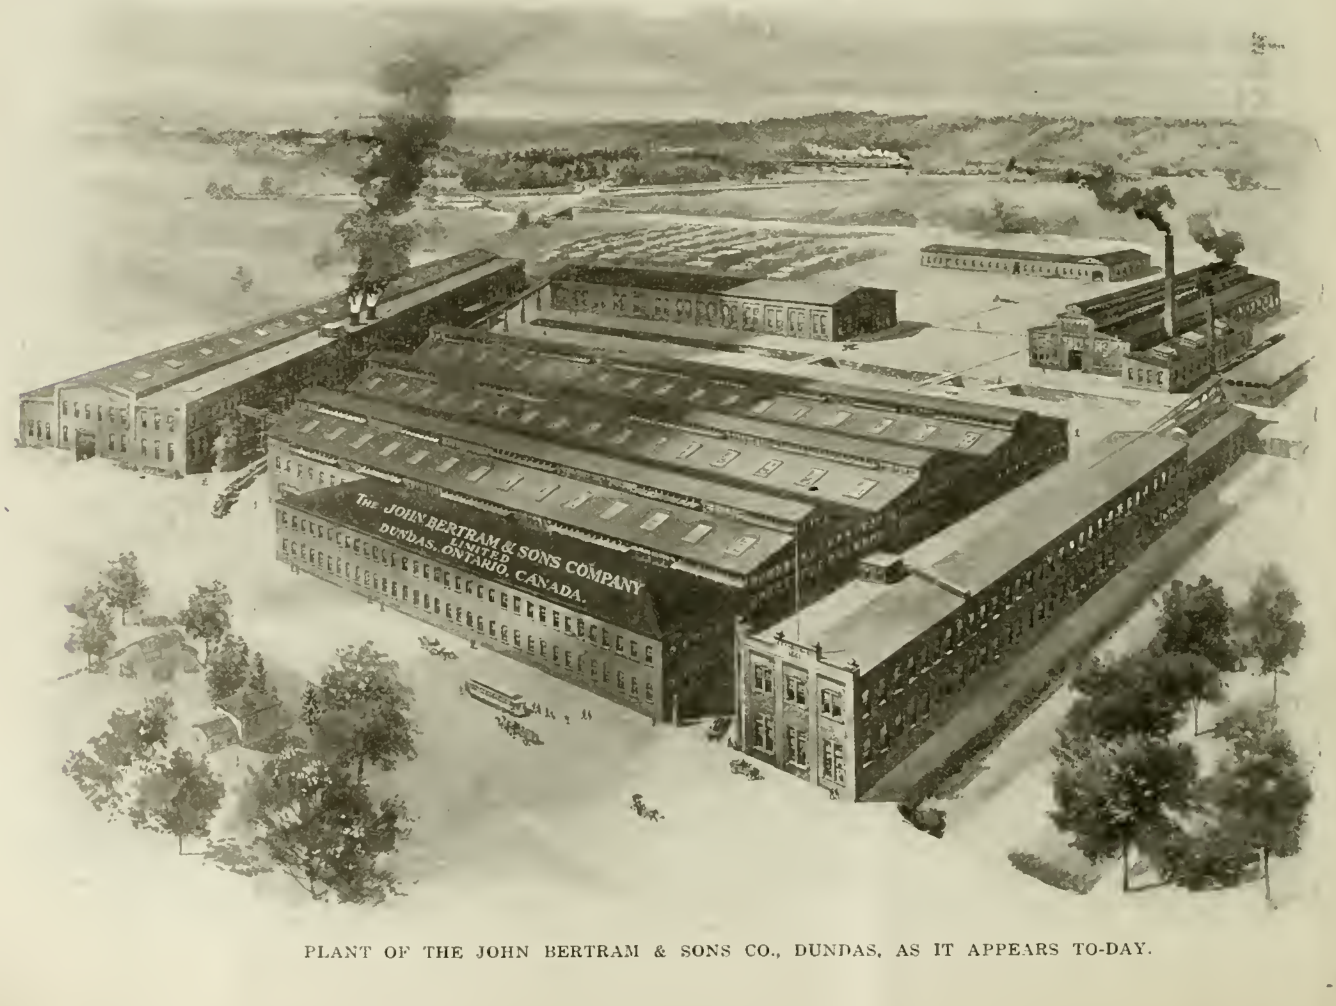
UP-TO-DATE TRIPLE DRUM SANDER.



UP-TO-DATE HEAVY DUTY SHAPER.

Robert McKechnie was one of the first presidents of the Canadian Manufacturers' Association, and with Sir John A. MacDonald, James Cowan, of Galt, Frederick Nichols, then a young man and secretary of the C. M. A., and a number of others, was instrumental in framing what is known as the National Policy of the Association.

In the political and commercial life of Canada, the district around Dundas furnished not a few men who later came into considerable prominence, among whom



PLANT OF THE JOHN BERTRAM & SONS CO., DUNDAS, AS IT APPEARS TO-DAY.

may be cited the Hon. Robert Spence, first Postmaster-General of Canada; the Hon. William Notman, who was known as the "Orator of the West"; the Hon. Adam Crooks, the Osler and McMahon families, Brig.-Gen. Sir Alexander Bertram, etc. To John Bertram was the organization and establishment of the Dundas Mechanics' Institute due, which quite early in its career became famous for its debating club and kindred activities.

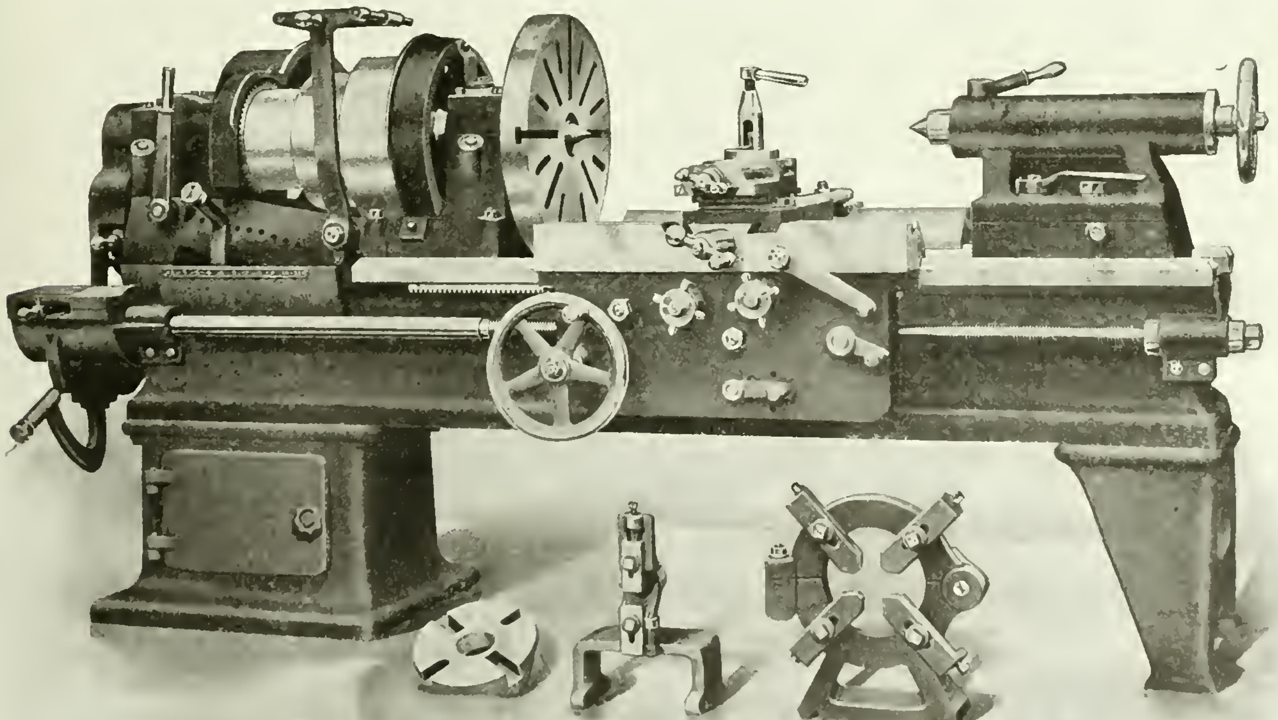
TENONING MACHINE.

Metal-Working Machine Tool Development Features

In the development of Canada's metal-working machine tool industry, the progress record of the McKechnie & Bertram partnership—followed later by the change of firm name to that of the John Bertram & Sons Co., has been largely that of the development of Canada's metal-working machine tool industry, hence the more specific references in what follows to the Bertram product.

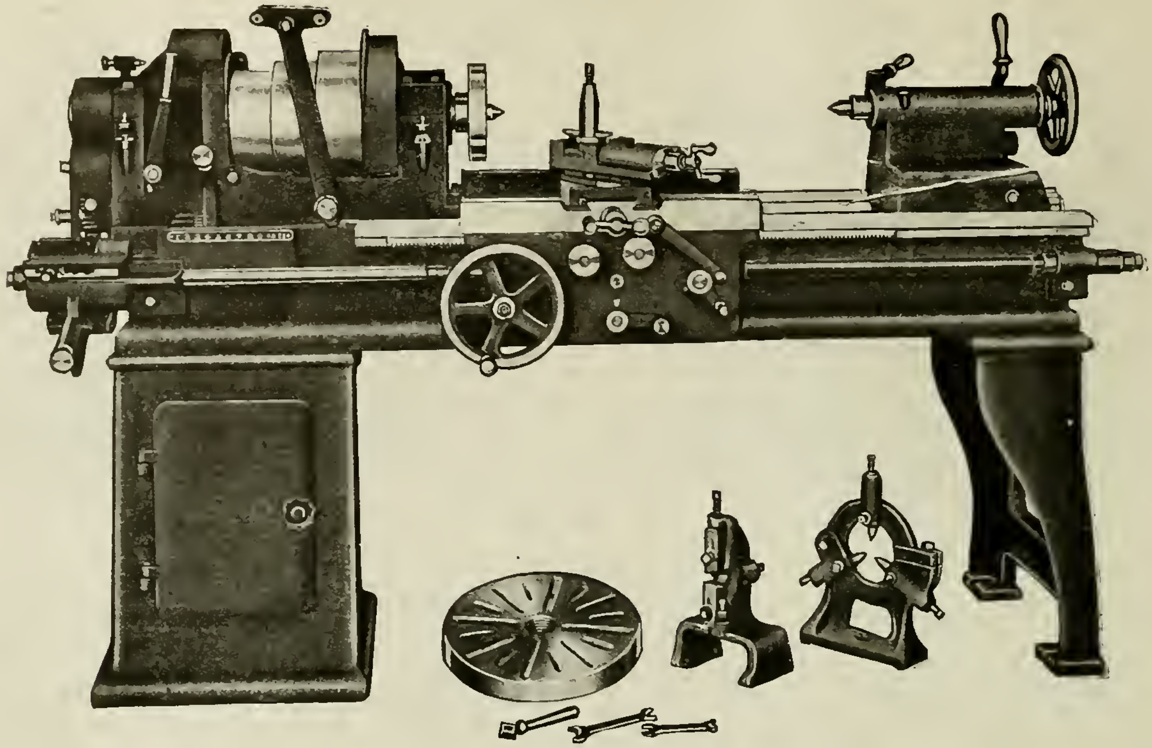
Being a mechanic with advanced ideas as regards achievement, John Bertram was apparently never satisfied with things as they were, being always at work on improved designs of product and looking to greater efficiency of plant organization and operation. It is interesting to note that quite early in his business career he set about the introduction of such aids to shop practice as Whitworth standard threads for taps and dies, besides recognizing the utility of employing plug and ring gauges for such services as sizing the bore of wheels and pulleys, and the turning of shafts. He also saw the necessity of employing cut gears, to which end he designed and built a gear cutter. This machine was of quite simple get-up, consisting of a bracket bolted to the shop wall, and carrying a mandrel and dividing plate. A man was trained to feed the cutter slide up and down, but it is recorded that he often made a slip and spoiled the gear as a result.

All keyways in the early days of the Bertram plant were cut by hand, and we are informed that not only was the quality of the work performed of remarkable precision and neatness, but the time

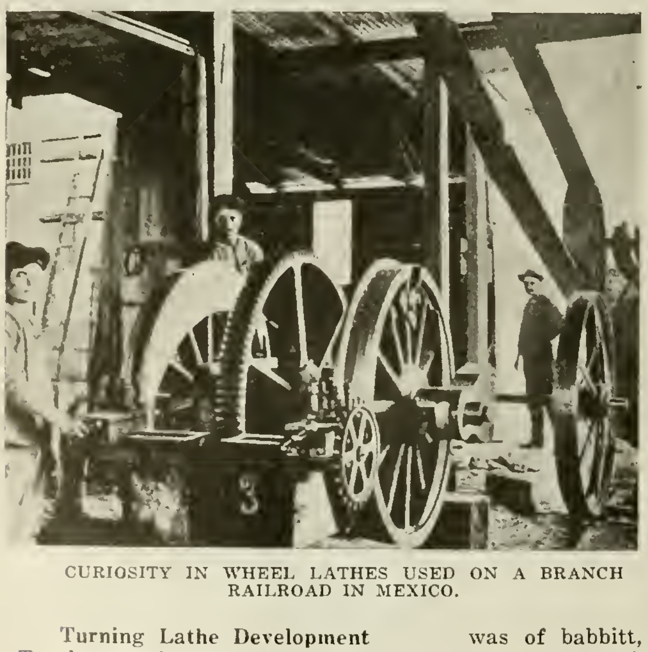


STANDARD LATHE FOR SHELL MAKING AND GENERAL MACHINE SHOP WORK.

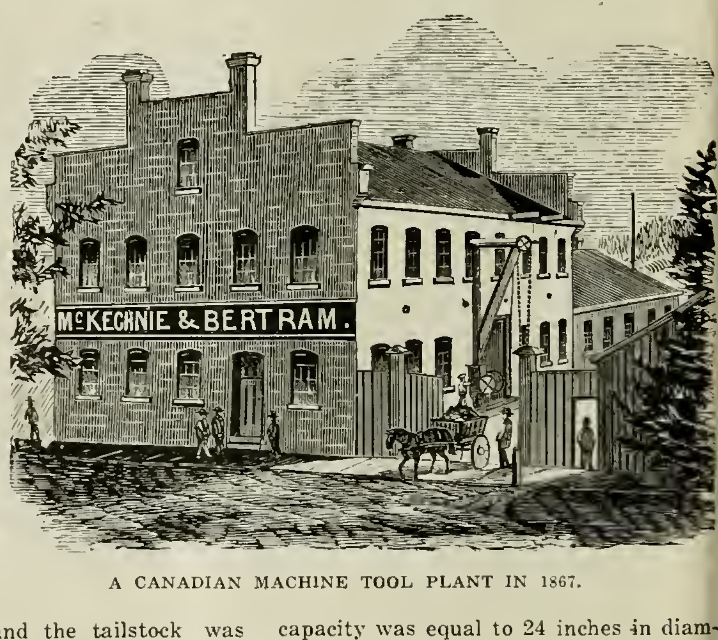
taken in cutting small keyways compares very favorably with present-day methods, when account is taken of the setting-up and machine preparation required to do the work. For duplicating keyways in change gears for screw cutting, a broaching tool was employed, the broach being driven through after the keyway had been roughed by hand, thus producing a standard finish which at least served the purpose. A milling machine for cutting keyways in shafts, and in which the various movements were hand controlled, may be said to constitute the next development of importance.



18-INCH QUICK-CHANGE, DOUBLE BACK-GEARED ENGINE LATHE.



CURIOSITY IN WHEEL LATHES USED ON A BRANCH RAILROAD IN MEXICO.



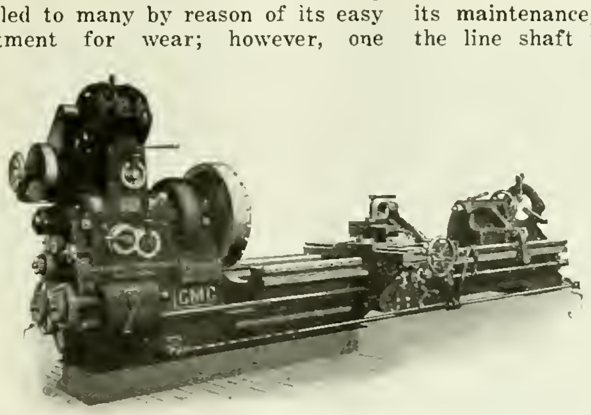
A CANADIAN MACHINE TOOL PLANT IN 1867.

Turning Lathe Development

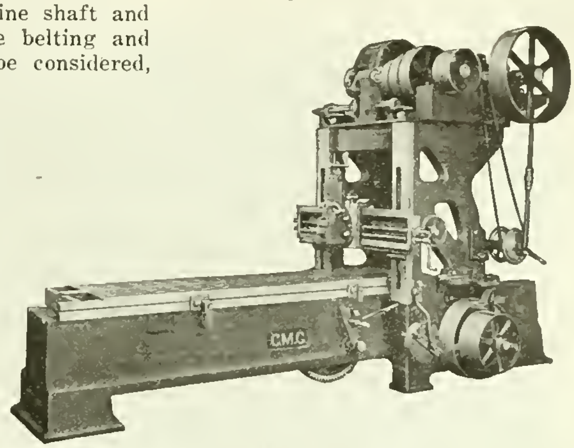
To the turning lathe, perhaps more than to any other unit of machine tool equipment, has special attention been given, and have improvements been more numerous and far-reaching, since the early "sixties." Then, we understand, it was considered quite satisfactory to furnish a 24-in. lathe with a flat shear bed, having single ribs connecting the ways together, a headstock having a four-step cone, a 2½-in. belt, and a gear ratio of something like 5 to 1. The spindle front bearing was 1¾ in. in diameter and ran in cast iron bearings; cast teeth were common to all the gears; the carriage or saddle had no power cross feed; the front apron was fitted with running gears of the most simple type; the lead screw nut was of babbitt, and the tailstock was fitted between flat ways. From the immediately foregoing sentences, and in the light of present-day achievement, it will be perhaps conceded without question that the turning lathe as such has been subject to and embodies bigger all-round improvement than any other of what constitutes the now extensive group of metal-working machine tools.

A type of lathe built until about the year 1885 was known to the trade as the flat shear engine lathe, the top of the ways of the bed having a flat surface. The carriage or saddle containing the tool block was gibbed at both front and rear to the ways of the bed on which it had its bearing. The ways were planed to an angle of 55 degrees. The swing capacity was equal to 24 inches in diameter. The cone and gear power were limited, however, when compared with the high speed machines of to-day.

In the early "seventies," two types of lathe head construction were freely discussed by machine tool mechanics in Canada. The conical or solid bearing appealed to many by reason of its easy adjustment for wear; however, one



MOTOR-DRIVEN 36-INCH TRIPLE-GEARED ENGINE LATHE.

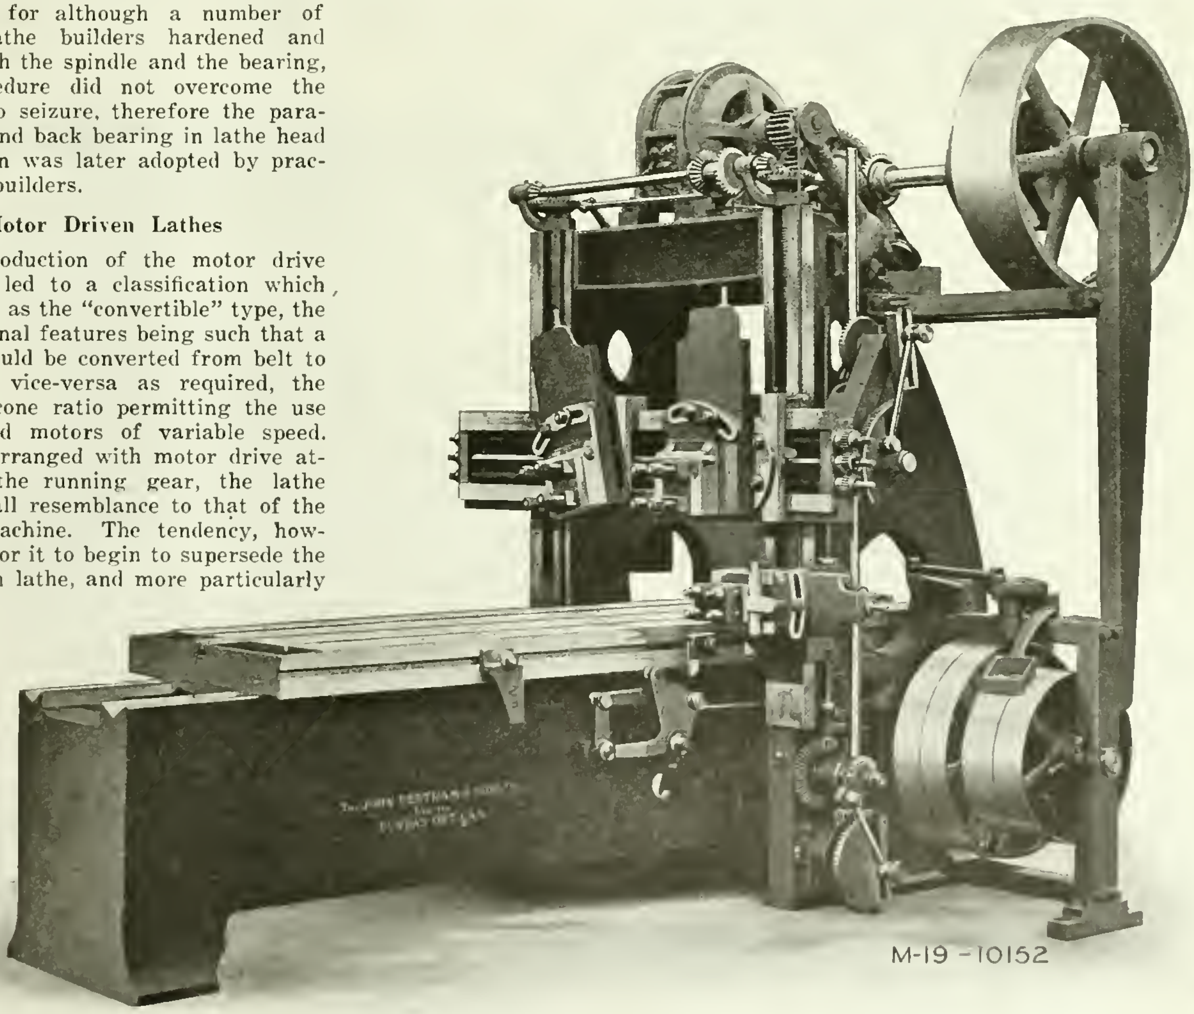


MOTOR-DRIVEN METAL PLANER.

element seemed to have been overlooked by those so impressed, and that was the matter of the expansion and contraction of the spindle under varying temperatures. This feature decided the fate of the conical bearing as constructed at that time, for although a number of English lathe builders hardened and ground both the spindle and the bearing, such procedure did not overcome the tendency to seizure, therefore the parallel front and back bearing in lathe head construction was later adopted by practically all builders.

Motor Driven Lathes

The introduction of the motor drive for lathes led to a classification which was known as the "convertible" type, the constructional features being such that a machine could be converted from belt to motor, or vice-versa as required, the gear and cone ratio permitting the use of standard motors of variable speed. When so arranged with motor drive attached to the running gear, the lathe head lost all resemblance to that of the original machine. The tendency, however, was for it to begin to supersede the cone driven lathe, and more particularly



36" x 36" STANDARD MOTOR DRIVEN IRON PLANING MACHINE.

in sizes running from a swing of 30 inches and upwards. Of course it is but reasonable to assume that some manner of gain was to be derived from the employment of motor drive, and in what immediately follows, a few of the advantages are enumerated.

Employment of the motor drive does away with the overhead line shaft and its maintenance, and since belting and the line shaft need not be considered, the machine may be placed to greater advantage in the shop and space thereby be economized. The range of speeds which are obtained by variable speed motors through drum type controllers enables the operator to arrange the cutting speeds to suit the material being machined. The speed variation is accomplished on the part of the operator by simply moving a handle which is conveniently located, a readily appreciated advantage as compared with changing the belt on the steps of a cone driven lathe. Again, in this as in all motor driven machines, the cutting speeds and feeds are materially increased, the power delivered at the cut by the motor being from 50 to 100 per cent. greater than the power obtainable in a belt driven machine; also, the absence of belt pull on the cone gives greater accuracy to the work being produced. The introduction of high speed tool steel has been responsible for increasing the output of motor driven lathes all the way from 30 to 50 per cent. and due to the latter feature, development has been in the direction of making all parts of these tools proportionately heavier.

PLANT OF CANADA MACHINERY CORPORATION.

Motor Driven "All-Geared" Type Lathe

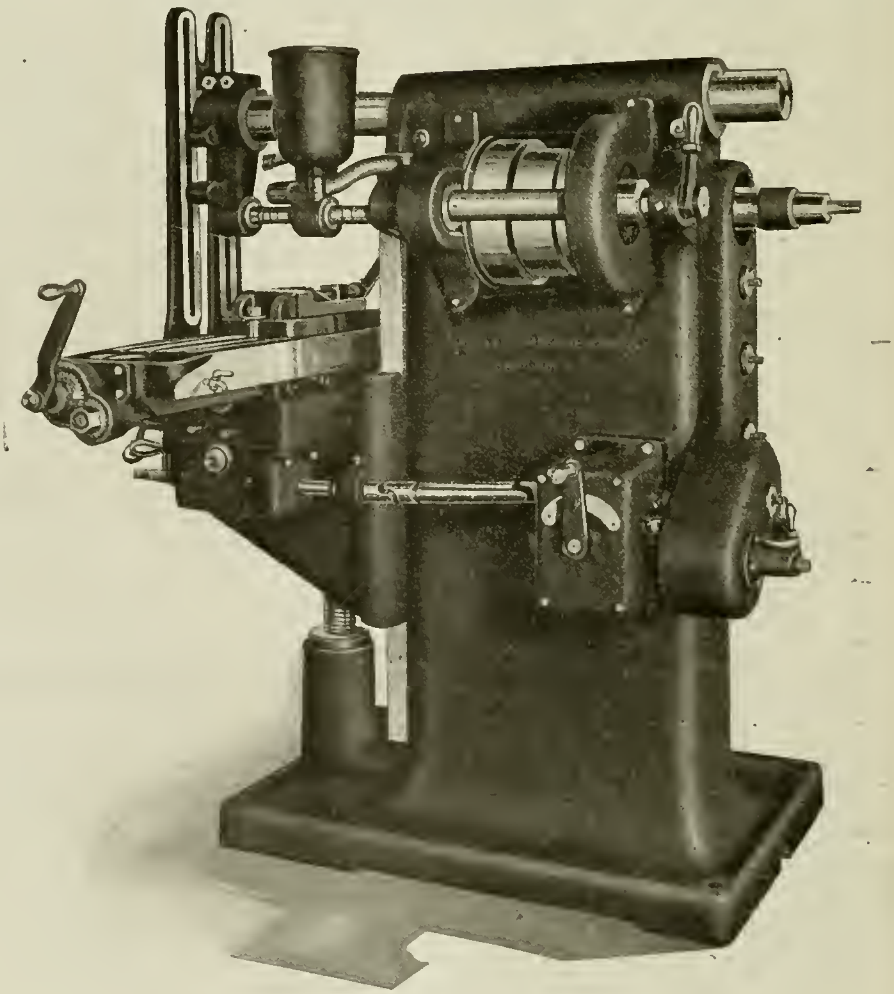
Tracing still further the progress record of engine lathe construction, that of the motor driven "all-geared," warrants some attention. The drive in its case was by constant speed motor or single pulley drive by countershaft. All changes of speed are effected by clutches, no changes of belt as on a cone being necessary. The construction was such as to commend it to users of lathes of very large size, although the number of gears necessary. The construction was such as furnished the groundwork of an argument unfavorable to its installation.

Locomotive and Coach Wheel Turning Lathes

Railroad progress and development may be said to have been responsible for the introduction of the locomotive and coach wheel turning lathe, the original design of which we are given to understand was to the credit of the Pond Tool Co., Plainfield, N.J. As first built, it was belt driven of about 9 horse power, and capable of an output of six pairs of wheels per day of ten hours. The special features of this are as follows:—

(1)—The central drive feature known, as the worm drive. The power is transmitted direct from the cone shaft or, as the machine is built to-day from the motor to a worm and a worm wheel, which is mounted on the end of the driving shaft. The end of this main driving shaft embraces a worm which in turn engages a large worm wheel in the centre of the machine. Both worms and wheels run in oil tight cases, which ensures perfect lubrication. In this way the power reaches the machine midway between the wheels, and, in addition to securing uniform power, the central drive makes it possible to support the wheels on both sides, the latter being accomplished by means of self-centering chucks which grasp or grip the axle journals, while chuck jaws engage the tires.

(2)—The compound rests which carry the cutting tools are mounted on the bed and are held by four bolts in T-slots; in this way any springing tendency is prevented, and in consequence the heaviest cuts can be carried. The machine has undergone radical changes,



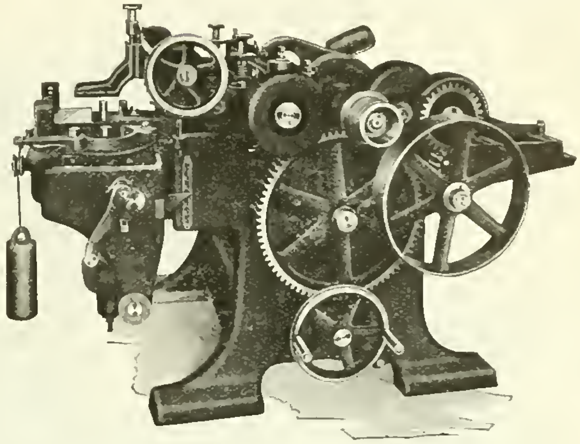
RECENTLY DEVELOPED CANADIAN DESIGNED AND BUILT MILLING MACHINE.

these having been brought about by the introduction of high speed steel and the use, for driving power, of an electric motor directly attached. As already stated, the original machine was capable of turning out six pairs of tires per day, but upon motor drive being added, the power was increased to 20 horse power, and the output increased from six to eight pairs of wheels per day, with one man as operator and one man as helper to roll the wheels in and out of the machine. For a number of years this was considered a standard day's work, but soon the energetic shop managers of the leading railroad companies increased the horse power to thirty, with the result that the output was increased to twelve pairs of wheels per day, this necessitating an additional helper to roll the wheels in and out of the machine. Not content with this progress, however, the power was further increased to from thirty-five to forty horse power, the output thereafter averaging 14 pairs of wheels per day, with two operators and two helpers. This while demonstrating the possibilities of the machine, also demonstrated to its manufacturers the fact that labor-saving devices must be added, the output having reached the limit of human endurance.

The first step in the direction indicated consisted of a new design of tool block clamping device for holding the tool, same being operated by compressed air to facilitate the work of the operator.

Power was also applied for both moving and clamping the heads on the bed. Next a segment in the central driving gear, which opens, closes, and locks automatically as the wheels are rolled in and out, was added. Labor-saving devices embracing those indicated and others not referred to have so perfected this machine that the output has steadily increased, until something like 40 pairs of wheels per 10 hour day are now turned out.

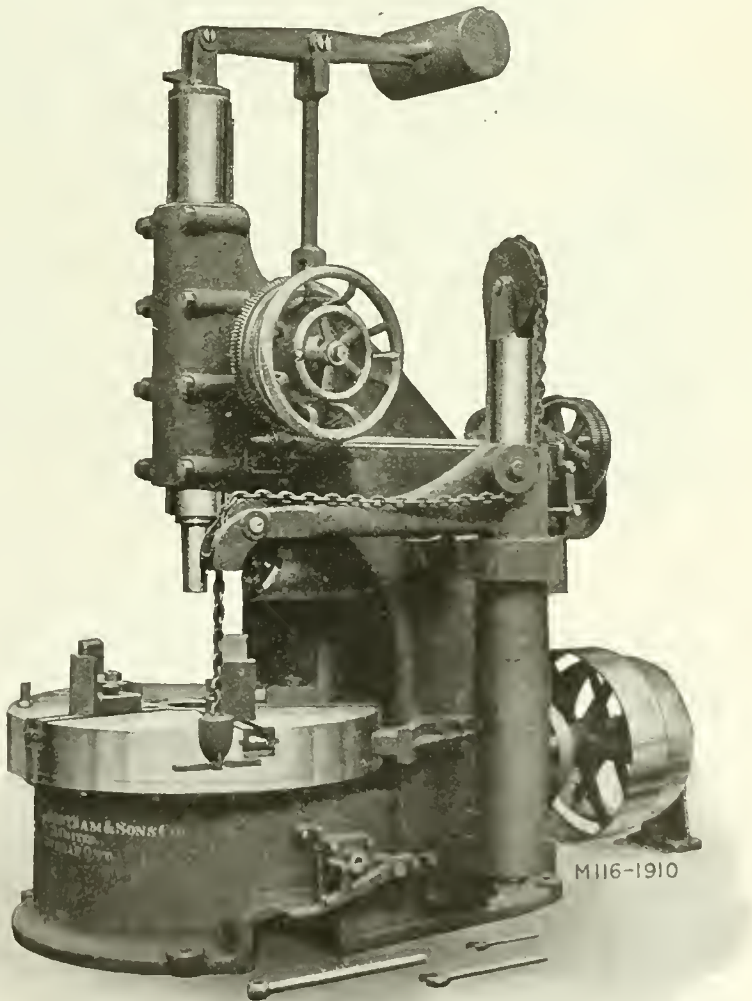
SAMPLE CUTTING FROM DRIVING WHEEL LATHE. WHEN 10 PAIRS OF DRIVING WHEELS WERE TURNED IN JUST OVER SIX HOURS.



SURFACE PLANER—WOODWORKING.

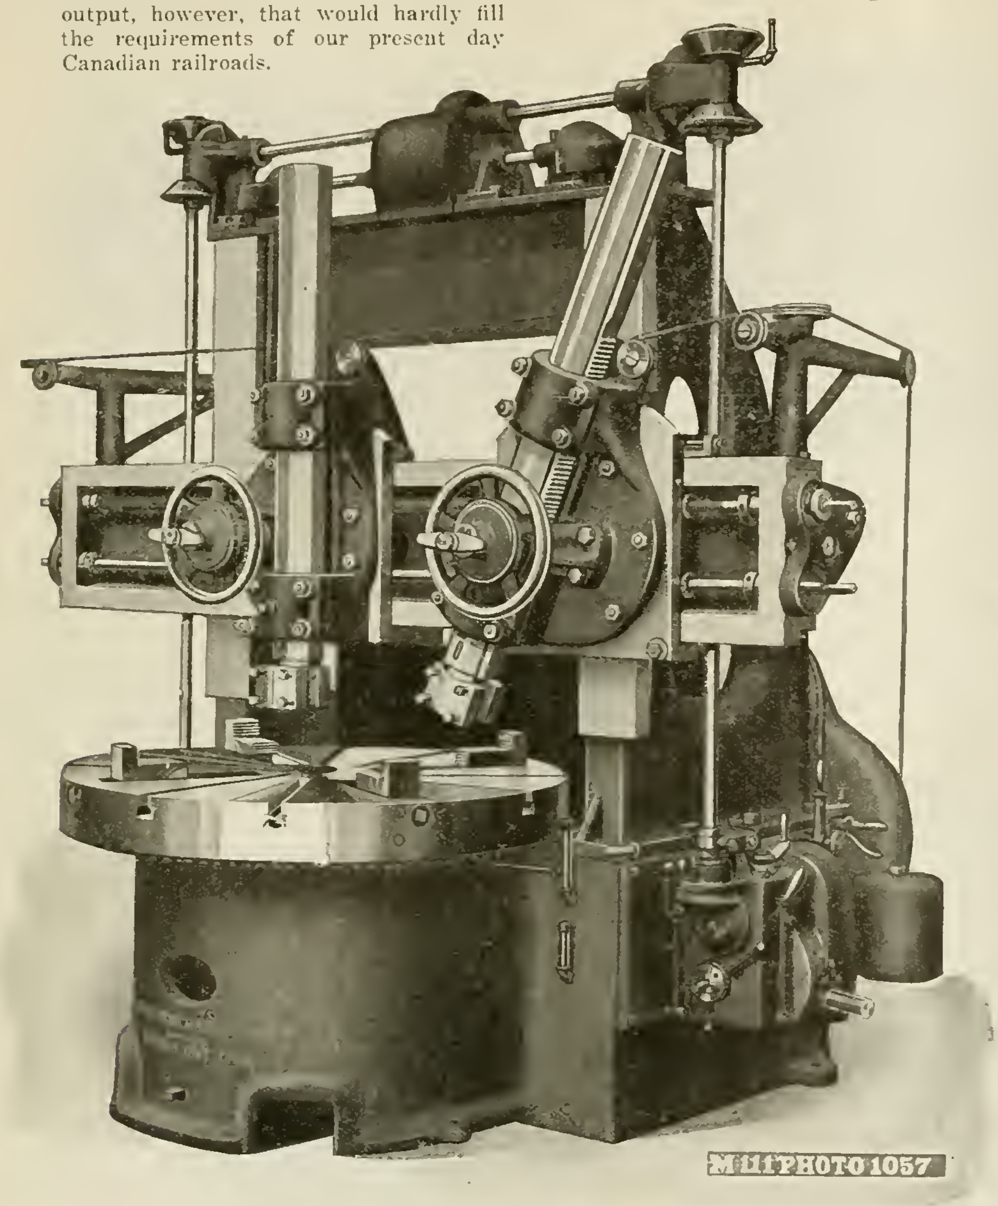
The wheel lathe originally designed for turning the tires of locomotive driving wheels was light in its various parts, particularly in the head and face plates. The power was limited, owing to the narrow belt by which the machine was driven, and the output was consequently limited to 1½ to 2 pairs of wheels per day. The top of the bed was a flat surface, and in consequence the pedestal carrying the tool blocks had to be of sufficient height to carry the tools to the center. Owing to their length in a lathe of 80 inches, this was an extremely weak feature, as it was scarcely practicable to make them of sufficient size and strength to prevent springing. This, together with the weakness of the driving plates and the primitive method of holding and driving the wheels, accounts very largely for the small output obtained.

The more modern 90 inch driving wheel lathe has been designed throughout with a view to obtaining the greatest rigidity at the point where the greatest strain is imposed; permitting of the use of very short and stiff tool posts. The back web of the bed, not being subject to so great a strain, is low; this facilitates the handling of wheels in and out. The tool blocks are equipped with a tool-holder, which renders easier the setting of the cutting tools; the operator being thus relieved of opening and closing four nuts each time the tools are set. The feeds are positive, being operated by connecting rods attached directly to the tool block feed shaft. The head is equipped with a 50 horse-power motor; the power is transmitted through a train of gears and a 7 in. shaft to the internal gears on the face plates. As the internal gears form wide flanges on the face plates, the plates are given great rigidity, and by the use of improved drivers, which hold the wheels perfectly rigid, the heaviest cuts can be carried with little or no vibration.



42-INCH CAR WHEEL BORER EQUIPPED WITH AIR CRANE FOR WHEELS.

In order to fully realize the improvement in the machine, it need only be stated that while the output of the earlier product was from 1½ to 2 pairs of wheels per day, the average output is now at least 6 pairs of wheels per day while, under special test, 10 pairs of driving wheels were turned out in just over 9 hours. One of our illustrations shows a cutting taken in the test referred to. Another illustration shows a wheel lathe from a photograph taken of one in service some years ago on a branch railroad in Mexico. The bed consisted of square timbers, a main gear in halves clamped to the axle at its centre, the wheels and axle running in their own journal. Claim was made that a pair of wheels were turned in one week, an output, however, that would hardly fill the requirements of our present day Canadian railroads.



42-INCH VERTICAL BORING AND TURNING MILL.

Turret, screwcutting , and tool room lathes, also single purpose lathes as a war time product of a myriad Canadian plants, and of wide variety design and scope, may be mentioned in passing as having participated in the lathe feature of our machine tool development.

Boring and Turning Mills

Boring and turning mills, another form of lathe construction, arranged to admit of easy chucking of work pieces to the faceplate, have shared to a large extent, in a variety feature, the labor and time saving attention given, and success achieved by the different type lathes discussed. Needless to say ,the tendency as in that of lathes has been also in the direction of more rigid and substantial general and detail part design and construction to meet the heavier duty requirements. It should perhaps be mentioned here that no Canadian firm at any time in its career has undertaken to manufacture what is generally known as a full line of metal-working machine tools, nor are we aware of effort being directed to the like end elsewhere. It is highly probable, however, that the Bertram works most nearly approach that condition.

Shapers and Slotters

The shaper is a straight line cutter of the planer type and is capable of performing a large number of operations formerly done by hand. The work is held stationary and the tool given a reciprocating cutting motion. The feed motion of shapers may be given either to the cutting tool or to the work. When the feed is given to the cutting tool, the machine is known as a travel head shaper. Crank type shapers may be said to embrace the line made in the past in Canada, and in their case as with all other metal-working machine tools, progress in design and weight of parts became necessary with introduction of motor driving and the employment of high speed steel cutting tools. Speed change gear boxes, and back gears, constitute other additions to the utility of shapers in more recent years.

Few machines which have to do with the production of the modern locomotive have undergone such changes in size, weight, and power, as the frame slotting machine, nor is this to be wondered at when the increased size and weight of the locomotive of to-day is compared with that of even only a decade or so ago. Naturally there was a corresponding increase in the size of the frame to be slotted. Previous to the year 1898, locomotive frame slotting machines built in Canada had a yoke opening of 34 inches wide by 12 inches high, and a bed length of 36 feet. The slotting of one pair of forged frames in 60 hours was the capacity rating. Since then, triple head slotters have been built here, and installation is to be found in our various railroad shops. Mention may be made of those in operation in the shops of the C.P.R., and Montreal Locomotive Co., Montreal. In the case of the first named, the yoke is 48 inches wide by 26 inches high, and the length of bed, 40 feet, giving capacity to slot four largest size locomotive frames in from 32 to 34 hours.

That installed at the Montreal Locomotive Co. plant has a yoke opening of 61 inches by 34 inches, a 50 ft. length of bed, with 32 inches maximum stroke of cutter bars. This machine capacity is the slotting of six locomotive frames simultaneously. The method of driving the slotter underwent a change for the better by the introduction of the electric motor. In the triple head machines, each head is driven by a 20 horse power motor, from which the cutting bars are driven through powerful friction clutches, permitting the operators to have convenient control of the bars at all times. This improved method of drive supersedes the long shaft which ran the entire length of the bed in the earlier machines. General purpose slotters, or as they may be classed—vertical shapers, constitute also a Canadian machine tool product, and in the case of their design, smooth running and rapid and convenient handling of the work have been kept in view.

Drilling Machines

As regards drilling machines of Canadian manufacture, it may truthfully be said that if not meantime, then at some time or other during the past sixty years, standard as well as many special types have been built, ranging from the common ratchet and drill brace, one of which is illustrated, having been in service here some fifty years ago, to the highest grade pedestal, horizontal, full universal radial, and gang drill presses, belt and motor driven. Drill press manufacture in Canada has perhaps been more widely practised than has any other form of machine tool product, many firms whose work has been of the most general nature, taking a hand in some feature of this wide-range specialty from the tiny bench or column drill upwards.

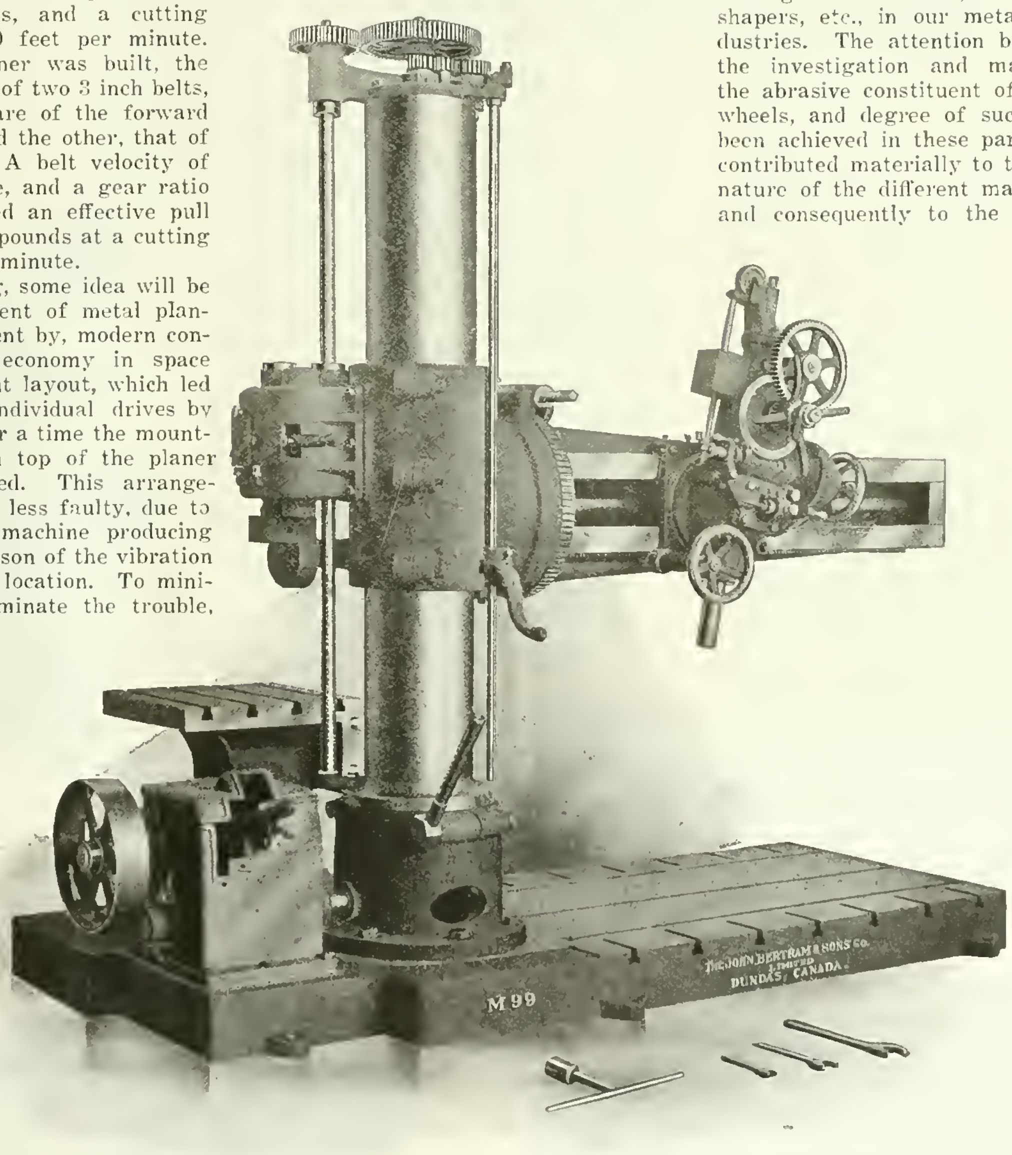
Metal Planers

It may not be generally known that planers belong to antiquity, nevertheless, on excellent authority we learn that little was accomplished as regards their development between the year 1694, and early in the year 1800. The planer at the Gartshore foundry already referred to had a cutting speed of 10 feet per minute, and the rack had a double section, the teeth of which were staggered to give a smooth and uniform motion to the table. One of the first metal planers built in Canada belongs to the year 1867, Confederation Year. The power was delivered to the table by a single 3 inch belt running at a velocity of 512 feet per minute, with a gear ratio of 6.25 to 1, giving an effective pull on the table of 3,750 pounds, and a cutting speed of table of 20 feet per minute. Later a 36 inch planer was built, the drive being by means of two 3 inch belts, one of which took care of the forward or cutting motion, and the other, that of the reverse motion. A belt velocity of 1,000 feet per minute, and a gear ratio of 13.4 to 1, delivered an effective pull on the table of 8,180 pounds at a cutting speed of 20 feet per minute.

From the foregoing, some idea will be had of the development of metal planers. As the years went by, modern construction demanded economy in space and a more convenient layout, which led to the adoption of individual drives by electric motor, and for a time the mounting of the motor on top of the planer housing was followed. This arrangement proved more or less faulty, due to the liability of the machine producing defective work by reason of the vibration caused by the motor location. To minimize or possibly eliminate the trouble, pneumatic clutches were introduced, and the motor drive placed at the base of the housings. The problem of providing the increased speeds and power to develop the possibilities of high speed steel, and to meet the necessity for greater production has been a comparatively simple one in such machines as lathes, drilling machines, boring mills, milling machines, etc., in which the cutting is continuous and the motion of the tool is in one direction only. In these types of machine, it has merely meant adding power, and strengthening parts. The speeding-up process introduces a vastly different problem in such machines as slotters, shapers, and planers, in which the cutting is not continuous and which have a return motion of the tool. The principal limitations of machines of this class, especially the planer, are twofold, there being first the inertia of the moving mass at the moment of reverse, and second, the speed at which the tool enters the work. The problem of overcoming these limitations has had the attention of quite a number of machine tool experts, and while considerable progress has been made, the complete solution does not appear to have been reached. The evolution of the planer has followed along the lines of increased table speeds.

Grinding Machines

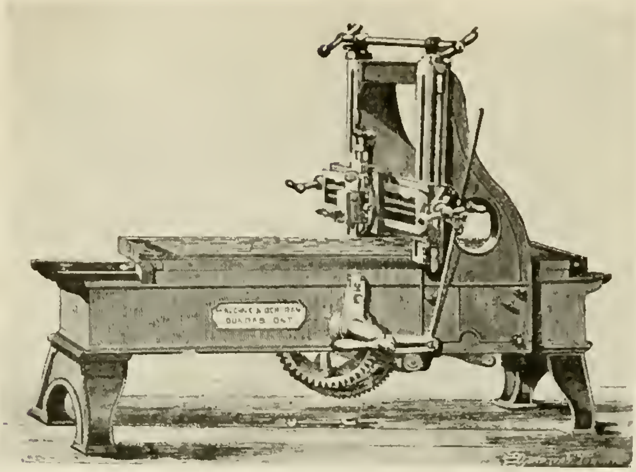
Grinding machines have proven to be well adapted for producing accurate work, and not only have they been found to be economical in the manufacture of machinery and tools, general and special but for duplicating parts on the interchangeable system, they are altogether unexcelled. Experience goes to show that it costs less to finish and fit work by grinding than by the old method on a lathe. Development of grinders in Canada compares very favorably both as to variety of product and its efficiency with what has been accomplished elsewhere, a circumstance which is highly complimentary to our different firms who have taken up manufacture in a specialised sense, thereby placing grinding machines, external and internal, on an equal footing with lathes, drills, planers, shapers, etc., in our metal-working industries. The attention being given to the investigation and manufacture of the abrasive constituent of the grinding wheels, and degree of success that has been achieved in these particulars, have contributed materially to the substantial nature of the different machine designs, and consequently to the accuracy and quality of the work produced. As in the case of the machines already noted, so with the manufacture of abrasive materials for grinding wheels, Canada can lay claim to having several plants in active operation.



6-FT. UNIVERSAL DRILLING MACHINE.

Milling Machines

It may be taken for granted that no machine shop having pretensions to the name of seeking to keep abreast of the

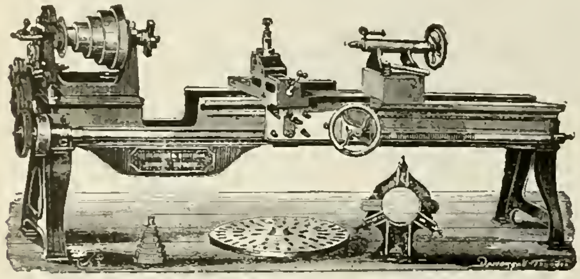


METAL PLANER BUILT IN 1867.

times is or should be without a milling machine as part of its feature equipment. An equally wide range of designs exists as in the case of the tools already mentioned, and naturally the variety of work that can be performed is commensurate. Milling machine manufacture in Canada dates well back into the Confederation period, but no very serious attempt appears to have been made by any one firm in particular to specialise until probably quite recent years. In the United States the miling machine has been highly developed, with the result that by far the greater number of those installed in our Canadian machine shops have come from there. One effect of the new vision of our manufacturing capacity that the machining of shells has produced is that we are competitively able to do what others have done or are doing; as an example, and directly relative to this milling machine feature, it may here be stated that one Canadian concern that less than a year ago started to specialize has now met with such success that milling machines are now their chief line, their output not only finding a ready market at home but abroad, shipping as they are into the United States against the tariff, also to Great Britain, Italy, India, France, Japan, Russia, etc.

Machine Tools for Shipbuilding

The impetus given to shipbuilding and



36-INCH GAP LATHE BUILT AT DUNDAS IN 1868.

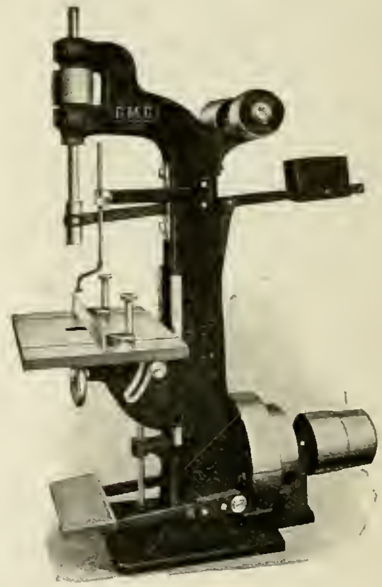
marine engineering in Canada, due to the submarine activities of Germany on the high seas, has naturally had the tendency to direct attention to the tool requirements of the twin industry. While such essentials as punches, shears, plate rolls and planers, etc., have been in the past produced here, same has been on a quite limited scale, particularly as the demand has been largely to meet the needs of structural steel, tank, and boiler plants. Shipyard tools are for the most part distinct from machine tools as commonly understood, less refinement being connected with their operation. Wood as well as steel shipbuilding is being prosecuted within our borders to an extent only a little less in degree as between the former and the latter. Already steps have been taken by at least one Canadian plant to cater to the needs of wood ship construction in the shape of a ship band saw being placed on the market and, as the opportunities are many for the employment of both wood and metal-working machine tools, it will be a very short time before a full line of each to meet the situation will be developed and made readily available.

General and Personal

It is of course impossible within the scope of an article such as this to even refer in passing to the many other units of metal-working equipment, attachments, and fixtures, not only found in our machine shops generally, but of Canadian manufacture in addition. Further, although some reference has been made to woodworking machine tool production in Canada, the fringe of it has merely been stirred, however, on some other occasion its detail progress may be given deserved prominence, by so doing there will be given evidence that equal achievement belongs to it as does to its twin-brother—that of metal-working.

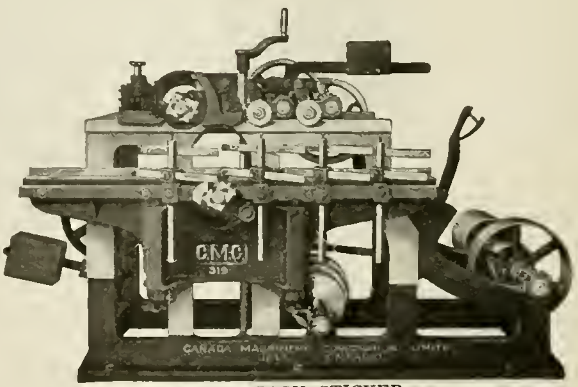
An important adjunct to the develoment of machine tool manufacture, whether the products be wood or metal-working, is that of the institution known as machinery selling agencies. By means of these the manufacturer is relieved both of the maintenance of a sales organization and in not a few instances of the necessity of finding work for his plant. Canada has been well served, we might say through the activities of selling agencies separate from her plant organizations, and that the agencies have maintained themselves from a date more or less well back into the Confederation Period, speaks volumes for the future welfare of the industry in its every aspect.

Before the advent of the lead screw on the early engine lathes, it was the practice, when small screws were required, to place the shafts between the lathe centers and by means of a hand tool and



VERTICAL BORING MACHINE.

(good judgment), make a slight impression of the required pitch over the surface; when this was accomplished, the



SASH STICKER.

shaft was taken to the bench and a helical groove chipped by means of a chisel to conform roughly with the desired thread, after which it was again placed in the lathe and the screw finished by using a flat chaser. Accuracy, so-called, was more of a human factor than it is now, the modern machine, irrespective of class or type being the acme of perfection, so to speak. In the early period of machine tool building, the achievement of accuracy was in the nature of an art. Many machine tools, both wood and metal-working built and installed away back as far as Confederation year are still in operation and doing good work comparatively, which indicates that they were suitably designed and constructed to give both long and efficient service.

There were boom and dull times in the early days of machine tool building just as there has been since, although due to township or district isolation, arising from the lack of railroad facilities, it often happened that the "hunger or the burst" was locational. That this was so on one occasion at any rate, and that the Canadian winters were a good deal more severe than they are now, is borne out by the story that follows:—New construction was more or less at a standstill in one of our pioneer plants, so with a view to keeping the rising generation of mechanics out of mischief, a disposition towards which had already become apparent, as also to keep them in touch with their work, arrangements were made to have them sent out individually to various firms who had been having tools built, and were themselves too busy to undertake their erection. Hot water, hot air (all kinds), and steam heat, were then unknown in Canadian hotels, as a consequence, sleeping quarters were unattractive to the extent that it is recorded of some of the "boys" that they did not undress for the period of one whole winter, and that on the occasion of a church social which no doubt had tractions common to the experience o most of us, the special dressing up meant simply the addition of a white shirt on top of the black working shirt.

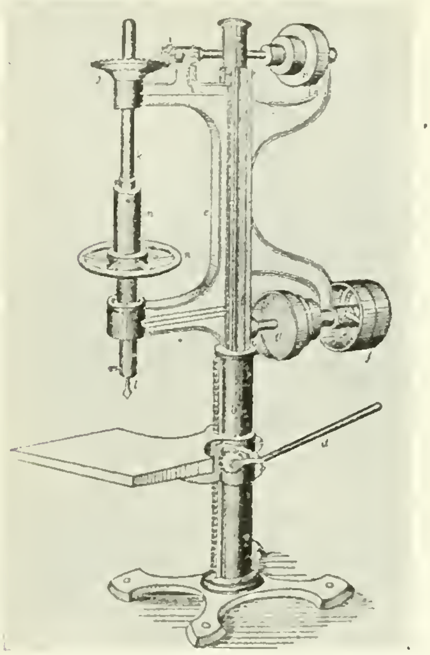
The majority of the pioneers of the machine tool industry have gone to their rest, large numbers of the youths they grounded in the essentials of the craft are however still with us, and it goes without saying that their presence, and the positions they now occupy, furnish the incentive to the youth of this generation to go in and win as they have.

METHOD IN MAKESHIFTS

By J. E. McCormack

IN one instance, in the replacing of water gauge fittings after renewal of adjacent parts, the squaring up of the replaced gauge parts was done by using a carpenter's square having a sixteen-inch tongue, which, by the way, was longer than the water glass used.

When the fittings were apparently true, a glass was inserted and in a few days the third glass had been put in, the former two having broken. The fact that this number of glasses had not been broken during the two previous years altogether proved that the fittings were out of line. Being an isolated plant, there was no proper try-square at hand. A man who had been working in a plant a few miles away called in and seeing one corner of a broken window pane lying on a box, picked it up, examined it on the carpenter's square, then with it he tested the fittings without removing the gauge glass. Through checking his observations by reversing the piece of pane frequently he detected the errors in alignment. The water glass was removed, the alignment adjusted by using the piece of window pane for a try-square, and the water glass replaced. During the following twelve months only one glass broke, and then only to the extent of a hole in one side and caused by a foreign substance of low



VERY OLD ILLUSTRATION OF AMERICAN-BUILT DRILL.

temperature coming against the said glass at this point.

The hint involved is, that in lining up articles for which a small try square is required but not at hand, it is sometimes possible to substitute some simple commonplace article and secure better results than could be obtained by the use of a square which though true is really too large for the amount of working room available.

By all means let us when possible have high grade tools—tools of a class designed for the purposes for which we require to use them but when we must substitute let us do so with an eye as to what can be quickly adapted to serve our purpose to the best advantage and without too much regard to actual market value so long as nothing is rendered useless for another time.

Resourcefulness counts when properly directed. Had a proper sized try square been quickly available, it would have been used in the first occasion mentioned above. The price of window pane had no market value but nevertheless it was more convenient than the square used and if it had been used at first there would have been time saved and the breakage and replacing of two extra glasses would have been avoided.

OPEN LETTER TO THE KAISER

A CORRESPONDENT of the New York Times writes the following open letter to the Kaiser, describing for his edification the advantages of the simple life on the Isle of St. Helena with its memories of other shattered dreams of world conquest.

You may go to St. Helena soon, I understand, but you are probably too busy fighting for your existence now to find much time for general reading. So I will tell you about St. Helena.

St. Helena is a pretty eight by ten island in the South Atlantic. The nearest land is Ascension Island, 700 miles away, and the nearest mainland Africa, 1,200 miles east. The best way to reach St. Helena is by boat. A battleship could drop you there and call back again once a month to see if you were all right.

The cliffs of St. Helena rise to the height of 1,000 feet, and the view from the top must be entrancing to a man who yearns as passionately for a free ocean as you do. You could stand up there and look at a free ocean for miles in any direction. As far as your eye could reach you would never see a submarine blowing up a passenger ship. The seas around St. Helena are probably the freest in the known world, and I hope you may be spared to enjoy the sight of them.

One of the nicest things about St. Helena is that it lies 4,477 miles away from England. While visiting the island you would not need to worry all the time for fear of being attacked by the soft, cowardly, rabbit-hearted English. You would not need to sleep in your spurs, with a gun under your pillow and your sword hanging on the foot of the bed, because England and Belgium would be too far off to jump on you without warning as they did so treacherously in 1914. After you had been at St. Helena a few years perhaps you would feel so safe that you could venture out in the yard without your weapons. There's no place like an island for a militarist with nerves.

St. Helena is really the lid of a volcano, but you have sat on the lid of a volcano for thirty years, so you wouldn't mind that. The climate is temperate and salubrious. The Hotel Longwood, where Napoleon stayed, is still standing. Queen Victoria presented it to the people of France some years ago, but doubtless it could be rented from the French nation. You need a good rest after your hard fight for the freedom of the seas, and I'm sure there is no place where you could get rest better than at St. Helena. The island was settled originally by pirates and about 3,500 of their descendants remain to this day, so you would have just enough congenial society without being overrun with it. Now I must close and take a run down to the bulletin boards to see if your brave little U-boats have made the seas any freer than they were yesterday.

PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

MILLING TWELVE SIDES ON LARGE DISC

By F. Scriber.

A FIXTURE of simple design for milling flats on a large disc is illustrated by sketch, Fig. 1. The work itself is shown by Fig. 2, from which it will be noticed the disc is 27 in. in diameter.

In this instance it was necessary to make the fixture cheaply, and in consequence a large angle plate A was used as a base from which to work. This angle plate bolts on to the table of the milling machine in the usual manner. On the beveled rib in the centre two machine steel blocks B were placed, these being held in place by screws and dowels as shown. The reason for putting these plates on is to build up sufficient metal for tapping into for the stud C.

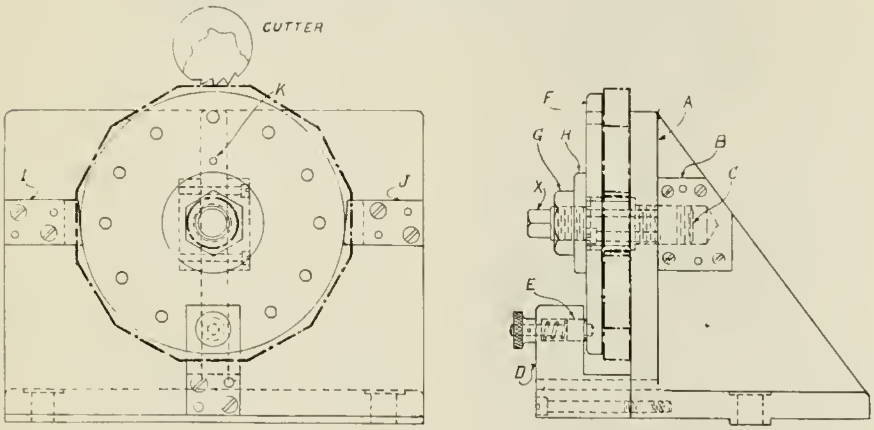


FIG. I.

To the lower portion of the angle plate a block D is placed; this block carries an indexing plunger E. A circular plate F is used for indexing, while a nut and washer G and H are used for clamping the work in position, two blocks, I and J, at each side of the large plate F being used as braces, while the large plate F and the work are doweled together by means of a pin K.

Operation of Jig

In operating this jig the large plate is first doweled to the work, and is dropped into the position shown in the fixture where the index pin E is forced into one hole in the large plate. While this is being done, the stud C, Fig. 3, is out of the fixture. The stud is now put into position, and with the nut G a couple of turns back, the stud is securely tightened into position by means of the squared end X. Ths stud forms an axis upon which the work may be turned for the successive stages of milling, as will be evident from the following.

After milling one flat in the usual manner with the cutter shown above, the nut G is loosened, but the stud remains tight. Then pull out pin E and turn the plate and work until the pin is forced in the next hole in the plate. The plate F and the work must, of course, turn together on account of their being doweled. The nut G is again tightened, and we proceed to mill the next flat, and by continuing this until all the flats, which are twelve in number are milled, the job is completed in a very satisfactory manner. After this the stud C is removed by turning on the squared end X, following which another piece is put into position, and we proceed to mill this piece in the same manner.

In further regard to the two blocks I and J, these bear against the periphery of the indexing plate, thus acting as braces to help to support the work while the cut is being taken.

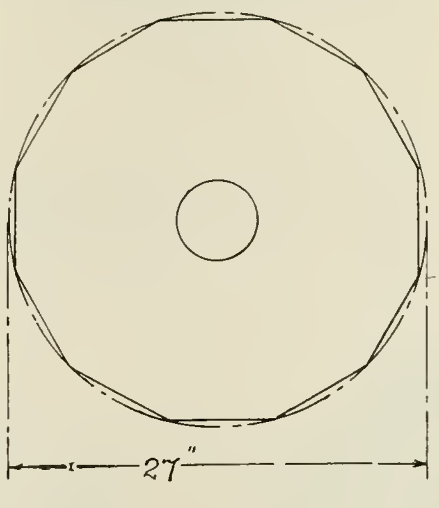

FIG. 2.

One big advantage in having this fixture built up as shown is that the various members may all be removed from the angle plate when the job is done, after which the angle plate may be again used for any purpose for which an angle plate is suited.

EYE-STRAIN AMONG DRAFTSMEN

By E. V. A.

EYE-STRAIN is a common complaint among draftsmen. It is a common fallacy that the constant use of the eyes in making drawings tends to weaken them. Experience and study has shown that there are other causes, more or less

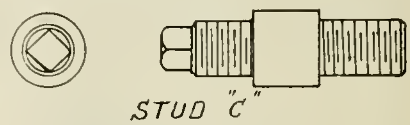

FIG. 3.

due to carelessness and thoughtlessness, which contribute to a considerable extent in weakening the eye-sight.

First of these is, working in a too glaring or inadequate light, this latter especially on stormy or cloudy days. Using lead pencils that are too hard, and which produce only light faint lines on the drawing. Using drawing paper that is too dark, making it difficult to observe the pencil-lines through cloth or paper when tracing.

While draftsmen may sometimes exercise no choice in the selection of paper and degree of hardness in pencils, it is necessary that those in charge of purchasing materials should be really careful to select only white drawing paper if tracings are to be made from it, or, if the penciling is to be taken directly from the board for use in the shop, the paper should be the lightest drab-color. Also pencils of various degrees of hardness should be kept on hand.

Pencils Should Suit Paper

The point to be emphasized is, that when paper of a drab-color is used, a lead pencil marked 3-H, or 4-H, should be used. Drawings that are to be traced should never be made with pencils of extreme hardness. The lead in a compass should always be one or two degrees softer than the pencil used, for the reason that one cannot bear down with sufficient weight with the compass to make arcs and circles equal in heaviness to the pencil used.

Modern drafting-room practice should not tolerate fine light lines on drawings. The day of fancy drawings made with web-like hair lines is passed. A blunt point on a pencil is far more serviceable —produces real "seeable" drawings— than the fine needle awl-like points that are commonly used. When inking a tracing, the lines should be made as heavy as possible. Figures and lettering, the most important part of a drawing, should be made large and "readable." Blueprints made from such tracings are much more appreciated by workmen who use them. Since no two persons' eye-sight is alike, it is readily seen that when the lines, figures and letters on blueprints or drawings show "big" the person with the weakest sight will be able to read them.

Another point that should be given careful attention is, that after a drawing is checked up particular notice should be taken to see that all lines, figures, etc., are sufficiently heavy, and where any are not, they should be returned and retraced for this purpose. Absolute plainness and simplicity should be the rule in making drawings. No drawing should be marked "approved" unless the points as described have been thoroughly examined to see if these have been properly rendered.

MACHINISTS' INSTRUCTION COURSE—XXII.

By J. Davies.

THE sector is a device for correctly dividing or measuring off a certain number of holes and is used in connection with the index plate. It is a labor saving device, and is designed to prevent any mistake in counting the holes The sector consists of two radial arms, so constructed that they can be set at any distance from each other and locked in position. Fig. 82 shows how the sector is used; to avoid any confusion the index plate in illustration only shows one row of holes.

We will suppose that the index crank has been adjusted and the circle of holes shown is the one selected. The latch pin is brought into the right position for a start, and put into one of the holes. Next

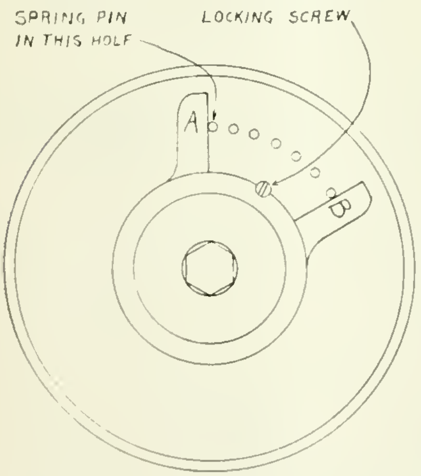

FIG. 82.

bring the arm A against the left side of the pin, then move the arm B forward the requisite number of holes and lock it in position. The illustration shows that the arm B of the sector has been moved forward 6 holes. Suppose it is required to use one whole turn plus 6 holes, referring to Fig. 82, the spring pin is withdrawn from the hole next to arm A, which is the starting place, and the whole revolution brings it to A again, the six additional holes bringing it round to arm B, arm B having been already adjusted and locked in position. Now put the spring pin into this hole next to arm B, and turn the sector round until the arm A is again up against the spring pin, after which the operation is repeated for every division required.

Compound Index

The use of a compound index makes it possible to obtain divisions that would be impossible with an index table used in the ordinary way, and it involves the use of two circles of holes instead of one. In one circle, the index crank and spring pin is used in the ordinary way; in the other circle the stop pin is used as an indica-

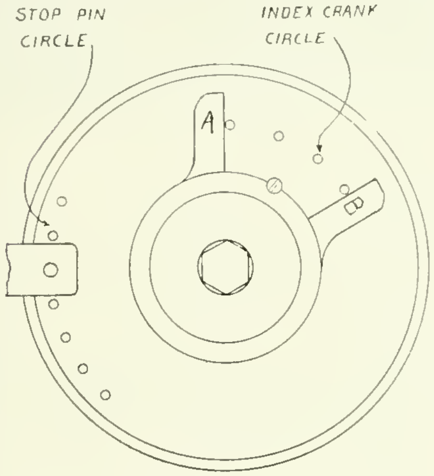

FIG. 83.

tor. In making the movements, after the necessary calculations have been made, first the index crank is turned round and put in position at the required number of holes, then the stop pin is loosed and the whole index plate turned back or forward a certain number of holes in this circle. The movement resulting from these two moves will be either their sum or difference. (See Fig. 83.)

For illustration, suppose circle No. 1 has been chosen with 40 holes, to be spaced off by the index crank, and circle No. 2 contains 39 holes, to be spaced off by the stop pin, if we move the index crank one hole we have obtained 1-40th of a turn. Now if we move the plate forward one hole on the 39 circle, using the stop pin as an indicator, the net result is that we have moved the index plate forward 1-40 + 1-39, or 79-1560 of a turn, a result that would be manifestly impossible to obtain by simple indexing.

Compound Index Calculations

Rule for calculating the moves in compound indexing:

1—Put down the number of divisions required and find all the factors the number contains.

2—Select for trial two circles of holes, subtract the number of holes in one circle from the number in the other, and find all of the factors for the number which represents the difference between the two circles.

Draw a horizontal line under these factors.

3—Find factors of the number of turns of the crank for one turn of the index head spindle and put them down under the horizontal line.

4—Factor the number of holes in the two chosen circles.

5—Cancel all equal figures above and below the line.

If all the figures above the line cancel out, the two trial circles can be used.

6—Multiply all the remaining figures below the line. This will give the number of holes to be used in each circle.

If all the figures above the line do not cancel out, other circles must be chosen for trial until suitable circles are found, or the combinations exhausted.

Applying the Rules

Example: Find circles and number of holes to be used to divide a job into 77 equal divisions by compound indexing, following the rules given above.

1—Number of divisions, 77, factors = 7×11.

2—Chosen circles, 49—44, difference = 5×1.

3—Number of turns of crank, 40, factors = $2 \times 2 \times 2 \times 5$.

4—Factor chosen circles, $49 = 7 \times 7$
$44 = 2 \times 2 \times 11$

5—Cancel all equal figures above and below the line.

6—Multiply all remaining figures below the line to find number of holes to be used = $2 \times 2 \times 2 \times 7 \times 2 \times 2 = 224$ holes.

224 holes in 44 circle—224 holes in 49 circle or $\frac{224}{44} - \frac{224}{49}$

$\frac{224}{44} = 5$ turns plus 4 holes.

$\frac{224}{49} = 4$ turns plus 28 holes.

Deducting an equal number of full turns from each side will not alter the

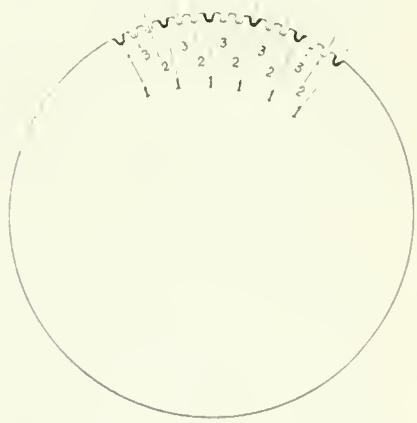

FIG. 84.

relative value, so that we have, after deducting 4 turns from each side, $1 \frac{4}{44} - \frac{28}{49}$

Now if we had done this job by simple indexing—that is, assuming it was possible—our fraction would have been $\frac{40}{77}$

so that if our compound index calculations are correct $1\frac{4}{44} - \frac{28}{49}$ should equal $\frac{40}{77}$

$1\frac{4}{44} = \frac{48}{44}$, therefore $\frac{48}{44} - \frac{28}{49} = \frac{40}{77}$

By cancelling we get $\frac{12}{11} - \frac{4}{7} = \frac{84-44}{77} = \frac{40}{77}$ — Ans.

It is sometimes necessary to do a job that cannot be calculated absolutely by thet index plates available. Such a case came under the writer's notice recently. A milling machine operator had a job calling for 81 divisions, so he cut 27 first (see heavy lines on Fig. 84), and then very carefully sub-divided, one division into 3 by direct measurement. Then he set his cutter to fit the measured division and went round again another 27 divisions, and repeated the operation the third time to complete the job.

FOUNDRYMEN'S CONVENTION AND EXHIBITION

WITH the total number of applications for space in the Mechanics' Building already in excess of the number of exhibitors at Atlantic City two years ago, and with the approximate floor area reserved considerably in excess of that occupied during that show, the success of the exhibition of foundry equipment, machine tools and accessories, to be held at Boston, September 25 to 28, is assured. Indications now point to the greatest show of this kind ever held, and it is probable that in number of exhibitors all records will be broken.

Manufacturers who have reserved space now are making preparations to ship their exhibits at an early date to avoid delays in delivery due to the congested condition of the railroads. As soon as delivered, all equipment will be stored in Mechanics' Building until the date of the opening of the show. An added feature of the exhibit will be the display of motor trucks. Manufacturers of these vehicles have been extended an invitation by the exhibition committee of the American Foundrymen's Association to display their products and a representative number of types undoubtedly will be displayed.

Technical Programme

That the technical features of this great gathering of foundrymen have not been neglected is reflected by the 44 papers that already have been secured, and to these must be added a large number of committee reports. The Boston meeting will be opened on Tuesday morning, September 25, in place of Monday afternoon, as at Cleveland last year, and morning sessions only will be held, closing Friday, September 28. Simultaneous sessions for the consideration of papers on gray iron, steel and malleable iron will be necessary to dispose of the lengthy programme that has been prepared. Registration will open at the Copley-Plaza on Monday morning, but on Tuesday the headquarters will be transferred to Mechanics' Building, where they will be continued throughout the remainder of the week.

ROLLING BRASS SHEETS IN A LARGE CANADIAN METAL WORKING PLANT.

Present Day Production of Metals and Minerals in Canada

By J. M. Wilson*

Despite restrictions of output and reductions in operating efficiency the mining industry of Canada has maintained its position well and in some respects where subject to war stimulation, its efforts have been greatly extended and widened. Metallic magnesium, metallic arsenic, ferro-molybdenum, Cobalt alloys, nickel refineries, all testify to the capacity and ability of the mining industry, presaging a future continuance of its present prosperity.

ABOUT a century and a half before Confederation, early French settlers carried on the mining and smelting of iron ore near Three Rivers in Quebec Province under a grant from Louis XIV. In 1915, there were 22 blast furnaces located in 12 separate plants, which in 1916 produced 1,169,257 short tons of pig iron valued at $16,750,903 the previous highest production having been in 1913, when 1,128,967 short tons were produced.

Despite its antiquity, and its present important dimensions, the growth of the iron and coal industry in Canada has been of comparatively recent date, the third quarter of the last century having seen numerous vicissitudes and successes in various parts of the country. The present day, however, sees the sister industries supporting the country in time of stress and, with numerous dependent activities, achieving an undreamed of development when compared with the proportions existing at Confederation.

Relative Importance

While the present state of activity will be subject to modification when normal conditions return, the mineral and manufacturing resources of the Dominion have greatly altered their relative positions in the country's trade, and in so doing have betrayed a welcome wealth of material which under other circumstances might easily have remained more or less dormant. A glance at the accompanying table shows that manufactures have advanced from fifth place to second place, increasing thirty-eight fold, and mineral produce now occupies fourth place instead of sixth, its increase being twenty-nine fold.

VALUE OF CANADIAN EXPORTS.

	1868-70 $	1915 $	Ratio
Agricul. produce, millions..	12¾	134¾	10.5
Animals and their produce.	9¼	74¼	8
Fisheries produce	3½	19½	5.5
Forest products	20¼	42½	1.9
Manufactured products	2¼	85½	38
Mineral products	1¾	51¾	29

The extent to which nearly all manufacturing industries are dependent on iron and coal for their existence lends additional interest to the value of manufactured exports, a value which reflects itself back through machines, chemicals, equipment, and power, to the earthly twins, iron and coal.

While not of such great value, the mineral produce is of particular interest, in that rare and commonly occurring materials are here found in more or less abundance, the variety being profuse indeed, and, with the exception of radium, vanadium, uranium, and platinum, including nearly every other mineral and metal found in any other country. Many of the products mined to-day were comparatively unknown to the world of science in 1867, yet at this moment are produced in large quantities, to play their part as essential substances in the world war, and later as mainstays of the Dominion's commercial life—nickel, copper, silver, gold, asbestos, and aluminum to mention a few only.

Coal and Iron Inseparable

Apart from their individual values to civilization, the interdependence of iron and coal is such that a review of either without the other would be incomplete, yet it is a peculiar feature that the greater part of the raw material used is imported; for instance, in 1914, 94 per cent. of ore, 50 per cent. of coke and 56 per cent. of limestone necessary for pig iron production was imported. In the early days, however, both ore and fuel were produced at or near the scene of operations, largely because of the undeveloped state of transportation, and for this reason we find the province of Nova Scotia early occupying the premier place amongst Canadian provinces as a producer of iron and coal.

As far back as the year 1604, the discovery of iron ore in Nova Scotia by one of the French governors of Acadia is recorded, but no real development took place until during the first half of the nineteenth century, during which several discoveries of ore were made until in 1880, iron ores were known to occur in fifteen of the eighteen counties of the province. The earliest record of coal in Nova Scotia is said to be in 1672, but apart from sundry efforts, no organized development took place until the year 1825, when a company known as the

*Associate Editor, Toronto.

General Mining Association, Ltd., of London, Eng., acquired all known and unknown minerals, except those previously granted. Circumstances subsequently enabled the company to secure control of all mines and minerals and insured the continuance of coal mining at the well known seams of Stellarton, on the mainland, and Sydney Mines, in Cape Breton.

Nova Scotia Districts

Mineralogical features and transportation facilities early combined to divide the Province of Nova Scotia into three districts known as Pictou, Cumberland, and Cape Breton, and up till the decade preceding Confederation, more or less intermittent efforts were made with varying success. In 1825 the Annapolis Iron & Mining Co. erected a 35 ft. stack at Clementsport, but after two years' operation closed down due to political influences, being stopped till 1860. Again in 1862, it shut down for ten years, resuming operations in 1872, when 600 tons of ore from a local mine were smelted, the resulting yield of 163 tons of pig iron going to Boston. White birch charcoal made locally, was the fuel, and fluxes were imported from St. John, N.B. This last effort only extended six weeks.

In 1828 an abortive effort was made by the General Mining Association to manufacture pig iron in Pictou county, but the first attempt which accomplished really tangible results over a term of years was that which resulted in the formation in 1874 of the Steel Company of Canada, with a capital of £500,000. This was one of the high water marks of a business which had its inception in a Catalan forge in 1850, followed by a smelting furnace with water power and charcoal fuel. producing seven tons of pig iron per day. The year 1860 saw a rolling mill added to the plant on the west branch of Great Village River; in 1862, a puddling furnace was added, the bars from which were shipped to Sheffield, and in 1867 a wheel foundry was installed. A subsequent reorganization, in 1887, due to market conditions, saw a million dollar company, the Londonderry Iron and Mining Co., to take control, but the depression of the early "nineties" was the beginning of the end, and only a pipe foundry remains of this extended but fruitless effort.

Concerns of To-day

The two concerns which now represent the iron and coal industry in Nova Scotia are the Nova Scotia Steel & Coal Co., and the Dominion Iron & Steel Co., the former operating plants at Sydney Mines and New Glasgow, and the latter at Sydney. The success of both concerns is largely due to one fact, viz., the availability of high grade ore from the Wabana mine in Newfoundland, but their histories vary much. In 1872, the town of New Glasgow saw the start of the Hope Iron Works near the scene of an unsuccessful attempt by the General Mining Association to smelt pig iron in 1828. By 1885 the business had developed to a point where the Nova Scotia Steel Co. was formed by the principal shareholders, with $160,000 capital and a 15-ton acid line open hearth furnace installed along with a 26 in. cogging mill and a 16 in. merchant bar mill. Here the first steel ingots in Canada were produced on a commercial basis, although basic open-hearth practice was adopted five years later, and the Duplex process more recently.

Up to 1889 imported pig iron had been used, but the formation of the New Glasgow Iron, Coal and Railway Co., in 1890 gave access to ore properties which were successfully utilized. In 1894, the Wabana ore fields of Bell Island, Newfoundland, were acquired, and since then the record has been one of continued progress, the present name of the company being assumed in 1900 after purchasing the coal and other properties of the General Mining Association in Cape Breton. Thus one of the most successful of the pioneer bodies was finally taken up by a later and much vaster organization, forming an interesting link with early times and imparting that touch of struggle and failure combined with ultimate success, which adds so indefinably to the prestige of old established yet modern concerns.

The production of coal from Sydney mines is an important feature, the annual production rising from 250,000 tons in 1900 to 840,000 tons in 1912, one third of this being used in iron and steel manufacture.

From Coal to Steel

The earliest development in this field however, was by the Dominion Coal Co., which in 1893 began active development of the most important coal areas here. It was due to a peculiar combination of circumstances that it was compelled to enter the iron and steel industry, the Dominion Iron and Steel, with a capital of $30,000,000 being formed in 1899.

The original plant was laid down for the production of blooms, billets and slabs, but was subsequently extended to produce steel in more finished forms. The Co. secured by purchase a portion of the Wabana ore deposits, this material when used with Sydney coal yielding satisfactory results.

Subsidiary enterprises utilize the by-products, over 5,000,000 gallons of tar from the six hundred odd coke ovens being handled, together with cement and fertilizer products from slag. From a production of 950,000 tons of coal in 1893, the output has risen to 4,500,000 in 1912.

Quebec Efforts

In Quebec province the blast furnace industry is almost extinct although intermittent efforts were made dating from the year 1737 mentioned at the beginning of this article. In 1867, Moise was the scene of an attempt to smelt iron on a commercial scale, likewise St. Urban in 1873 and Hull in 1872 and 1887, all of which were unsuccessful. At Radnor and Drummondville, however, furnaces were operated continuously from 1887 to 1912 on local ore, with locally-made charcoal as fuel, an average output of 8,000 tons per annum being maintained. The present industry consists of steel production in small open-hearth furnaces and electric furnaces, also the manufacture of special steels the tonnage of which is relatively small.

Ontario a Success

Operations in the Ontario iron and steel industry are unique in the fact that all fuel used together with the greater part of the ore used is imported. Geographical features have divided the plants into two groups the Ontario, and the Lake Superior. Numerous deposits of ore have been found in Eastern Ontario and many of these in Mayo township are shippers.

The early efforts to establish the iron industry date from 1800 when an attempt was made in Leeds county. Normandale was also the scene of a failure a few years later which, however, was more or less redeemed between the years 1832 and 1847 during which time it was successfully operated on bog ores of the vicinity with charcoal fuel. Other efforts were the Marmora furnace 1820-1875, Madoc, Houghton and Burnt River being also the scenes of ultimately abandoned efforts.

In 1892 the province of Ontario was without a single blast furnace, but from 1894 when smelting was started in Hamilton, followed later by the Lake Superior activities, the growth of the industry has been steady. The Ontario district now contains seven blast furnaces, the Steel Company of Canada, in 1913 producing 180,000 tons of pig iron. 157,000 tons of steel ingots, and 192,000 tons of finished merchant bar.

Western Developments

The Lake Superior district contains four blast furnaces, three of which are operated by the Algoma Steel Corporation, Sault Ste. Marie. An idea of the extent of the development at this point will be gathered from its output figures for 1913, pig iron made, 308,000 tons; coke made from American coal, 411,000 tons; steel ingots made, 438,000 tons; steel billets made, 20,000 tons; rails made, 320,000 tons; merchant mill product, 19,000 tons. A considerable amount of native ore is mined in this district, the Helen mine in the Michipicoten range being the largest producer in Canada, with 1,000 tons per day, other shippers are the Helen and Magpie mines, northwest of Sault Ste. Marie, while the Moose Mountain range contains an important deposit of magnetite.

The amount of iron ore mined in Canada in 1913 is not insignificant despite the troubles of pioneer efforts. In that year, 307,000 tons were produced but since then, New Brunswick and Nova Scotia have ceased. Ontario produced 195,000 tons of that amount. Helen and Magpie mines shipping 22,000 tons and Moose Mountain 3,300 tons. In 1914, 244,000 tons were produced in Ontario of which 184,000 tons were shipped to Canadian furnaces and 60,000 tons to the United States.

Mineral Developments

Canada was a gold producer of some

importance at the time of Confederation, the output for the five preceding years being 882,947 ozs., valued at $18,252,143. British Columbia produced more than seven-eights of this amount, Nova Scotia suplying the balance. Quebec became a producer in 1877, Yukon in 1885, Alberta in 1886 and Ontario in 1891. In these the Yukon has the record for any one year, 1,077,553 oz. in 1900, valued at $22,275,000. By 1914, Ontario had secured premier annual place with 268,305 oz. valued at $5,546,356.

Ontario has a well established lead in silver since 1906, till now she is seven times as productive as British Columbia the figures in 1914 being 24,215,926 oz. and 3,212,111 oz. respectively. in copper, the positions are reversed, British Columbia producing 41,221,628 lb. against Ontario's 28,948,211 lb.

The history of nickel has been recapitulated so frequently of late that further emphasis on its value as a national asset seems impossible in these columns.

Unique Source

Talc, graphite, gypsum, feldspar, mica, corundum, molybdenite, ashestos, and manganite are some of the minerals now produced commercially throughout the Dominion. The world's chief source of asbestos is in Quebec, and with the exception of Ceylon, Canada is the only source of supply of amber mica, the United States securing its supply of this very necessary material for electrical work almost wholly from the Dominion.

Adding to these the existance of petroleum and natural gas on a considerable scale in certain localities, the variety of our natural resources becomes more evident, and when modern develonments is water power utilization are taken in consideration, the whole industrial complexion assumes a wonderful aspect in comparison with fifty years ago, a surpassing roseateness dimmed only by the world cloud of struggle but ever holding forth promise of future brightness and greatness which in other fifty years may well outshine the present, even as the present outshines the past.

FIRE LOSSES LAST MONTH

LOSSES by fire in the United States and Canada last month reached the stupendous total of $24,968,000 just $9,000,000 more than the corresponding month of last year.

In these figures are included the values of many expensive Canadian factories and industrial concerns. The rapid growth of the monthly fire loss is causing grave concern. In these days when the country is straining every effort to reach a maximum production, the loss of a single factory is felt, and it is urged that a campaign for great fire prevention be immediately launched.

Losses So Far

The losses in the United States and Canada, according to The New York Journal of Commerce, for the first five months of 1917 reach the unusually large aggregate of $129,108,455, as compared with 113,528,920 for the same months in 1916. The following table gives a comparison of the losses for May of this year with those of the two preceeding years, together with the losses by months for the balance of 1916 and 1915:

	1915	1916	1917
Jan.	$20,060,600	$ 21,423,350	$ 36,431,770
Feb.	13,081,250	24,770,770	29,587,660
March	18,786,400	38,680,250	17,523,000
April	18,180,350	12,681,050	18,597,225
May	11,388,450	15,973,500	24,968,800
Total 5 mo.	$81,497,050	$113,528,920	$129,108,455
June	$ 10,893,950	12,247,500	....
July	9,006 800	23,013 800	....
Aug.	10,067,100	10,745,000	....
Sept.	14,823,500	12 244,625	....
Oct.	14,465 850	17,701,375	....
Nov.	21,204 850	19,898,450	....
Dec.	20 877,100	22,063,325	....
Ttl. for yr.	$182 836,200	$231,442,995	....

Big Fires in May

There were some 261 fires during May each of which caused an estimated property damage of $10,000 or over. This compares with 244 such fires in April, 270 in March, 381 in February and 303 in January, making a total of 1,459 fires since the first of the year, which caused a loss of $10,000 or over. The May fires classified according to their destructiveness, show the following results:

Estimated Loss	No. of Fires
$ 10 000 to $ 20 000	71
20 000 to 30 000	53
30 000 to 50 000	41
50 000 to 75,000	31
75 000 to 100 000	19
100 000 to 200 000	26
206,000 and over	20
Total	261

Of the twenty large fires during May which each caused a loss of $200,000 or over, the following are worthy of special notice:

Location—Description—	Amount.
Columbus, Ohio, department store	$ 300,000
Pocatello, Idaho, garage and 200 autos	340,000
Toronto, Ont., ammunition factory	350,000
Sioux Falls, S. D., grain warehouse	1,000,000
Macon, Mo., railroad station, etc.	550,000
Lexington, Ky., several business houses	600,000
Atlantic, Ga., dwelling section of city	5,000,000
Fort William, Ont., stove Works	500,000
Bowie, La., lumber yards and dwellings	1,000,000
Greenwich, Conn., dwelling	300,000

Practically all of the important fires in May involved well insured property, and the fire underwriters, who had suffered severely in the first quarter of 1917, are now much worse off.

Ontario Figures

The summary of fire losses in Ontario during the first four months of the year is as follows:

	No. of Fires	Loss	Insurance Loss	Loss not covered by Insur.
Jan.	798	$ 808,419	$ 566,589	$241,830
Feb.	1,020	1,369,139	1,105,039	264,100
March	765	1,144,373	886,126	258,247
April	666	1,201,361	998,384	202,977
Total ...	3,249	$4,523,292	$3,556,138	$967,151

While the aggregate amount of the April loss ($1,201,361) is in excess, it is gratifying that the number of fires in the province in the mosth of April is less by nearly one hundred than in the preceding month, declares the report of the Ontario Fire Marshal. Unfortunately, the aggregate of the fire loss is due almost entirely to two large fires, both of which are under investigation. In Hastings county, Graham & Company's evaporator at Belleville was burned, involving a loss of about $185,000. In Norfolk county, the loss is almost exclusively caused by the fire in the premises of the Dominion Canners at Simcoe. It has not yet been ascertained what the exact amount of the loss by this fire is, and we are consequently estimating it at the figures furnished in the official Fire Chief's report, namely, $23,000 on the building and $500,000 on the contents. This may be very far astray, but it is the official estimate and when the loss is determined, it will be adjusted in the subsequent month's return.

CAR SHORTAGE IS SERIOUS

Representatives of the various Boards of Trade and the railway companies are to meet in Ottawa on July 3rd, to outline a plan for revising the existing car demurrage rules. If an agreement can be reached the Railway Commission will be asked to ratify the new regulations immediately. It is felt that if the present rules are not changed car shortage will become more acute month by month.

"The public should have a clear realization of what is aimed at in the revision of these demurrage rules," said J. E. Dalrymple, vice-president of the Grand Trunk, recently.

"The situation is unprecedented. In every territory on the continent there is a demand for cars that cannot be fully met. It is useless to look to the car builders for relief. They have more work now than they can handle. If the situation is to be improved, or at least prevented from becoming more serious, there must be the greatest possible cooperation betwen the shippers, the consignees and the railways. Every car available must be kept moving and every car must be loaded to its capacity. That is without doubt the only way out of the present difficulties. Any measures that may be adopted to prevent the undue holding of cars for loading and unloading will, therefore, be of national advantage. Rules that were probably equitable under normal conditions are to-day hampering the efficiency of transportation."

FUNDAMENTALS OF EFFICIENCY

By J. E. C.

An efficiency system, as generally understood in the machine industry, means a system or plan, designated by such terms as scientific management, industrial management, etc., installed for the purpose of increasing production. Under these captions are included, motion-study, time-waste, and other expressions too well known to need mentioning.

Efficiency in its broadest sense is something that has to be developed, and relates to several conditions and things, each separate in themselves, each subject to close scrutiny and observation—finding out where their particular waste and inconvenience lie, and improving these according to their needs. By this particular method do we arrive at the point where efficiency is to begin, or to state it more clearly, where a saving is to be had, where production can be increased, and where that which is now a wasteful method, is overcome.

Expense Origination

When a factory whistle blows, or the power starts up, it may be said the factory expense begins, at least its heaviest item, the wage expense. If the workman is precisely there on the moment to start his machine, and continues steadily at his work until the power shuts down again, it may be said there is no loss or time-waste taking place so far as his labor account is concerned.

While it is quite impossible for anyone to work without a certain amount of relaxation, nevertheless this describes the point exactly, whether there is or is not a loss. In other words, it may be said that efficiency means a gain, inefficiency means a loss.

It is through the overcoming of these losses that gains or savings are made. Getting as much out of the workman, compatible with what is reasonable and humane, from the time he enters the factory till he leaves it, is what counts in profit or loss of any machine concern. Whatever he does, whatever he handles, whatever is convenient or inconvenient to him, in the way of tools and accessories, are all a part of this given study. It makes little difference how much has been done, or is being done, in the way of improving methods, or, more properly speaking, what follow-up system is used in eliminating waste, reducing time in operations, the principal part is the state of activity in which workmen perform their labors, the amount and kind of "exertiveness" they display while doing their several tasks. Now a workman can pick up a wrench quickly or slowly. He may move as one always ready on the minute, or be slovenly disposed in what he is doing.

Workmen's Dispositions

No two workmen are alike in their movements in any factory. And because of this it can be pointed out how far short production fails in its accomplishment. And yet this is the precise point that needs mostly to be looked into. There is a certain rhythm and steadiness that can be followed and practised in any occupation which will result in a considerable saving in time. It must not be construed that this is what is called grinding down or squeezing the utmost out of workmen—far from this. It means simply developing in him a taste for healthy energetic activity. It is working out a firmness, a preciseness in every effort he makes, even in every step he takes, moving swiftly and surely, or to state its fullest meaning, being always sure-footed, exact, prompt, free from any hesitation, always on the alert.

These are the fundamentals of efficiency work. They mean something more even than being dexterous or being possessed of an aptitude for doing certain classes of work.

The word "exertiveness," mentioned above, specifically states the effective sense and meaning of cultivating increasing efficiency along any line of manufacturing.

It spells power, a combination of physical and mental force that acts energetically in whatever employment one is engaged in. One may ask, can a workman be all these things, and constantly so, throughout the course of one day even? Would this not be a harmful proceeding? Would it not result in a physical breakdown? To this it may be answered, that no one ever did overwork, or felt any harmful effects therefrom. As much, even if not more, harm has come from being shiftless, lazy, and lacking interest in one's work, because this leads to or is being inefficient.

Any one of these things stagnates the human frame. A physical break-down is seldom if ever the result of overwork. History records no instance of any great man—and most every great man has been a worker, being carried off by overwork. On the contrary, the greatest loads have been carried, the most tremendous tasks have been accomplished, leaving the worker still ready and alert to tackle something still greater.

An Incentive Necessary

It is possible to train workmen to be exertive. Behind this lies the main principle which attaches to itself the real importance for effective efficiency. In doing this, of course, one must look at the main purpose. What is the main purpose? From the workmen's point of view increased activity must mean something more besides increased activity. It must mean increased compensation. Increased compensation means awakened interest. And it is interest, interest alone, that awakens the blood, sets moving faster and making richer the red corpuscles that circulate in the veins and arteries of the human body.

Interest, then, is the secret of efficiency, exertiveness follows as a matter of course. On the other hand, the principal thing is to keep interest alive. How to do this need not be gone into here. If it is necessary to give workmen intervals of fifteen minutes' rest twice a day it should be done. If it is necessary to shorten their hours of labor it should be done. Where interest lags or becomes deadened, efficiency follows suit; it begins to drag; the wheels of industry become clogged in their bearings. Beyond and above all is interest.

A case in point may be cited in regard to ammunition workers. The complaint has been called forth that the production in shells is nowhere near the amount possible. Why? Because they have already made so many that they have become deadened to the work. And yet, what are they making shells for? Is it not for themselves? Are they not working for the same ends as those who are firing them? This fact has been emphasized, been bought home to them time and again, yet has it resulted in any noticeable speeding up on their part? Very little. Their failure may be laid to the fact that the thing most lacking is exertiveness. They have not been trained to exert themselves; trained to set their pace so as to be producing to capacity every moment they are engaged. In their particular case they should be "doing their bit" and a little bit more, for in this they are as much heroes as those engaged with the enemy—their work is heroic action. Each represents so much man-power per unit in the present world's great conflict.

Key to Efficiency

To sum up, exertiveness is the key to efficiency, the mainspring to productive activity. The direct opposite of being listless. It is the direct line in which good and efficient workers are made. The creation of this man-power is applicable to industrial work, and will develop a class of workmen vastly superior to those who at present move in a monotonous routine or are left to act on their own initiative. To enthuse workmen by some incentive has always been the outstanding mark towards which employers must incessantly strive. But aside from personal profit and financial gain the constant exercise of exertiveness on the part of a worker will greatly tend to increase his efficiency; smooth away his rough edges; from being slow gaited, he will become lively-stepping; will concentrate his mind on what he is doing, on the motions he makes; and by so doing will increase his worth and value, both to himself and his employer.

BY-PRODUCT COKING

By T. J.

AMONG many branches of development in modern scientific industry there is probably none of which less is known to the general public than that of by-product coking—that is to say, of the manufacture of coke on a large scale for use in the blast furnace and the foundry, and of the contingent recovery of valuable by-products from the coal used. Formerly all coke for use in the metallurgical industries was made in "beehive" ovens—a considerable portion of it being yet made by this primitive process, in which a considerable portion of the carbon, as well as the volatile elements given off under the influence of heat are consumed to keep up the temperature of the oven. The only product of this system, therefore, is a remainder in the form of coke, amounting usually to about 60 per cent. by weight of the coal put into the oven.

About thirty years ago the by-product oven was introduced, and more recently it has made such progress concurrently with improved methods of recovering and treating the by-products that at the present time the larger proportion of the coke production of Britain is made under by-product recovery conditions. The essential difference between the two systems is that while the older one is a burning process (with necessary limitations as to the amount of air admitted to the oven), the newer one is purely a distillation process involving external heating and the total absence of air; and whereas the product of the one consists of coke only, that of the other, besides a larger quantity of coke from a given weight of coal, includes also, in some cases, a large volume of surplus gas, in all cases valuable residuals in the form of coal tar and ammonia, or ammonia compounds, and in may cases benzol which is the principal "intermediate" of some of our most powerful high explosives, and of many varieties of coal tar dyes.

Among other things, little known to the public, is the large part which is being played by the by-product coking industry both in helping the Allied nations to win the war and in keeping going many of our most important industries under war conditions.

By-Product Ovens Surpass Gas Works

The popular idea is that the principal source of ammonia and toluol, for example is the gas works of the country. In point of fact. the by-product of coke ovens, and certain closely allied processes yield more both of coal tar and ammonia than all the gas works of the country combined, and much more of benzol and toluol, which they are able to recover from their gas more systematically and thoroughly than the gas works can from theirs. Altogether, there are now about 120 by-product coking plants in Great Britain, comprising about 8,000 ovens, each carbonizing a coal charge of from eight to ten tons in from 30 to 36 hours, or approximately five charges per week. As the operation of the plants is continuous the potential yield of metallurgical coke per oven per year, allowing liberally for all contingencies, and for occasional repairs, may be taken at from 1,200 to 1,500 tons, so that the aggregate output may be put at approximately 10,000,000 tons.

In some cases the ovens have regenerators; in some they have not. In the latter case the greater part of the gas given off in the process of carbonization is used for heating the oven flues—in the former only about half is required for this purpose, so that there is a large volume of gas available for consumption under steam boilers (thus again saving coal), for use in gas engines, or for sale. In several cases the surplus gas is cheaply sold to power companies, and raises steam for the generation of electricity; in others it is transmitted to iron and steel works for heating purposes, in others, again, it is sold to the statutory gas authority of the locality for the town lighting.

The town of Middlesbrough is now wholly lit by gas from the coke ovens of Messrs. Samuelson & Son, Port Clarence Works, and the supply of the City of Leeds is partly derived from the coke ovens at Middleton Colliery some miles away. Generally speaking also, each ton of coal distilled in the by-product oven yields from 7 to 9 gallons of tar, from 24 to 32 lbs. of sulphate of ammonia, and in the majority of cases now, from 1½ to 2½ gallons of benzol, which is sometimes sold to chemical works in crude form, and sometimes fractionated on the spot to commercial benzol, totuol, xylol, and solvent naphtha. Some of the plants have also their own distillery, and some recover naphthalene or ammonium chloride.

No actual figures can be readily given, but it may be affirmed with confidence that the by-products thus recovered on modern coking plants in England. Wales and Scotland. represent an annual value of $10,000,000 (all of which would have been lost in the "Beehive" oven process). There is also the consideration that to produce the same weight of coke under the old system at least a million tons of coal would have been required, an important consideration at this time, when the supply of coal is unequal to the demand.

THE AEROPLANE AS A MEANS OF COMMERCIAL TRANSPORT

By L. E.

RECENT developments in aeroplanes, both as regards engine power and improved construction, have caused many to wonder whether this generation or the next will see fleets of aeroplanes acting in the capacity of commercial transporters. Will developments which the war has produced in aeronautics, enable the industry to contemplate any other market for its wares than naval and military? Developments prior to the outbreak of the war clearly showed that the tendency was to concentrate on evolving a satisfactory instrument of war, and in the odd leisure moments left to manufacturers since war broke out, they have doubtless contemplated the use of the aeroplane in new directions, but it is certain they have not had time to go into the matter closely. Perhaps in a few months' time they will have more leisure for this subject—perhaps they may not.

In the case of the immense Russian Sikorsky biplane, there is promise of a machine more especially designed for peace than war and in the institution of an official aerial service for mails in 1913 by the French Minister of Commerce between Paris and Nice, there was another attempt to employ the aeroplane in the utilitarian rather than a military way. Apart from these few efforts made in those days before the war, the fact remains to-day that the aeroplane is not yet an instrument of commerce.

Progress in science is always going on, but at present it has been directed to the ends of war, and until the war comes within measurable signs of finishing the demand will be more and more insistent; nevertheless, it is interesting to enquire why there has not been some attempt made to make the commercial aeroplane possible.

What Limits Progress?

Some investigations were made in the year 1913 and the result was bluntly announced that the aeroplane could never be a commercial vehicle of motion for either passengers or goods, but no enquiry has yet been made as to the actual source of hindrance. No one has yet touched the spot where progress in this direction is retarded. Yet even scientists in Germany are proposing to use airships rather than aeroplanes for their much vaunted service between Germany and the United States. It would be interesting to know why they have decided against the aeroplane. Let us see what we can find out as to the causes of hindrance up to the present.

Until recently the difference between the ideally constructed aeroplane and what was turned out of the shops was very great. The realization of the ideal would be for each one part of the machine to have one, and only one, function to perform. The wings of a flying machine are primarily a means of obtaining lift, but in the majority of machines the rolling of the machine is controlled by warping the wings—a really crude way of relieving the designer's ideas. True, the designer is restricted by what the constructive department can do, and they again are restricted by the materials in hand. All questions of improvement resolve themselves into one of the material, and if all the secrets of existing new materials could be revealed, it would probably be found that there is now a light strong alloy which makes possible the construction of the wings and their entire covering of metal.

Further, there is the question of motive power. The evolution of the light powered motor, occupying a small space, has been fairly successful, but better ones will be turned out in the future when the experience gained in our army and navy has been collected and distributed. But efficiency is only one side of the question. The total power consumption is even more important. With an improvement in the construction of the body and wings of the machine, a certain lessening of the horse-power required will follow automatically, and this, with the improved efficiency of the engine itself, should perceptibly decrease the running charges—really the greatest bar at present to the use of the aeroplane commercially, for this expense is quite out of proportion to its dividend earning capacity.

Minimum Power Record

According to some investigations into aeroplane records, the lowest power used on an aeroplane was 9 horse-power, with which Mr. A. V. Rowe actually accomplished, in 1907, some flights with his triplane. No one in his senses would dream of repeating the experiment, for it is only at high speeds that there is any approach to safety, so that it is even rare to find a horse-power nowadays under 50, or even 70.

The aeroplane, to be commercially successful, must yield the small cost of the 9 horse-power machine per passenger, or per hundred weight of goods carried. For example, instead of carrying 1½ cwt., or 80 kilos, the 100 horse-power Doutre machine on the Paris-Nice mail service would have to have its load increased to 15 cwt., and the Silkorsky biplane would carry about 150 passengers instead of 15 with a horse-power of 400—but at the sacrifice of speed.

Because of the manifest impossibility of considering that point at all, the acceleration of the mails between Paris and Nice has a financial value that cannot be estimated at all for there is no data to go upon. On the other hand, it might be regarded as just to neglect the speed factor, for it is only possible for the aeroplane to travel at high rates of speed with safety; the inability to move slowly may be as much on the debit side of the account as the rapidity of motion on the credit side. Nearly all the machines at present in use are undoubtedly stronger and safer than those used in the early years of the present decade, and presently an entirely new principle of obtaining sustentation may be evolved or some method of further developing and applying the propulsive power. The high costs of running, increased for the moment by the cost of oil, petrol and labor, may limit the aeroplane, for the present, to those uses and duties in which high and speedy flight is required for itself alone, but there is no reason to doubt its use as a commercial means of transport in the not far distant future.

The speed of an aeroplane is, of course, vastly superior to other modes of travel; though its arrivals and departures are liable to be affected by weather conditions, and whilst its motion might be easier for the human body, its special qualities will be available for many branches of commercial work. In the future we may see regular fleets of airships and aeroplanes in practically daily use, and then we shall wonder why we never used them earlier.

A SPECIFIC INSTANCE OF SPECIFIC GRAVITY

By J. E. McCormack.

WHEN the writer tells anyone that he has seen solid pieces of iron actually floating on liquid—yes, solid pieces of iron actually floating on liquid" — he takes grave risks of having his word doubted, but the story is really true. Not expecting to see such a thing at the time, he poked with a stick to make sure if what he saw was foreign matter, and floating. He then removed one of the pieces to ascertain its nature, and, upon finding it to be iron, put it back into to liquid again to make sure if it did float, and float it certainly did. A little common sense readily explains the phenomenon, but occasionally a fellow may not happen to be thinking of common sense when first looking at exceptionally uncommon occurrences. We are so accustomed to seeing iron sink that we do not expect solid pieces of it to float of their own accord under any circumstances and this fact might lead some one to sometimes quite innocently make the same experiment that procured for the writer the privilege of seeing iron floating.

The paper frictions of a certain machine needed re-filling and for this purpose were sent to a machine shop in another town. When they were returned one of them was too large to allow its shaft to go down into the bearings properly. Its neighboring friction wheel worked below it and therefore the remedy adopted was to re-babbitt the bearings, but with the shaft lined up an inch or more higher than before, the caps of the bearings being shimmered, or packed up accordingly. As this left a large space to be filled a couple of pieces of old sleigh-shoeing were put in the bottom of each box to help fill up the space and thus save babbitt. The scheme happened to work all right. Probably some of the blocking that supported the shaft was resting on these irons instead of the shaft having been supported by independent blocking placed outside of the bearings.

Some year later, when the frictions had become worn down considerably, the writer undertook to re-babbitt those same bearings, putting the shaft down to near its proper place again. The old babbitt was dug out and melted again for re-use (the shaft being one that ran at only a moderate speed), and as the specific gravity of the babbit was greater than that of iron those long forgotten pieces of old shoeing floated. I wonder by just how much (or little) one or more of them escaped rising up against the shaft while the melted babbitt was flowing around them. If anyone doubt the possibility he is at liberty to drop some spikes or some chunks of iron into a ladle of melted lead or babbitt some time and see for himself if the iron comes to the top or not.

The moral intended is: If anyone has an exceptionally large space to fill with babbitt, don't attempt to fill part of it with old iron without making sure to block it well away from the shaft itself for keeps, whether above or below, lest he afterwards finds that in places he has an iron to iron contact in his newly poured bearing.

Had it not been for the above experience, he would probably even yet have expected that iron placed in the bottom of a space about to be filled with babbitt would remain there even if depending only on its own weight to hold it down. He would probably not have mentally compared the specific gravity of the two metals.

REMOVING BROKEN SET SCREWS

THE quickest removal of a broken set screw ever witnessed by the writer was accomplished by a special tool made from an overgrown three-cornered file. About two-fifths the length of the body of the file had been broken off its smaller end, and the newly broken end on the larger piece ground down to a pyramid shape. Most of the tang was also removed. This tool had been made some time before and for this class of work. The other tools used were, a drill, a lever, and a wrench. The diatmeter of the drill used was possibly half, but not more than that, of the smrew to be removed.

A hole was first drilled in the centre of the broken screw, deep enough to give the special tool a chance to work without its point coming in contact with the bottom of the said hole. This special tool was then placed with its sharp end in the hole and the lever placed inside the frame of the machine and across the tang of the tool, then pressure applied to force the tool into the hole. The tool was then turned backwards with a wrench. At first it acted like a countersinking tool, but soon got hold of enough metal to enable it to give the broken screw a turn and the job was soon finished.

On paper the job looks bigger than it really is. A large three-cornered or square can be easily made into one of these tools and if a size strong enough for the work, will last indefinitely. The drill, wrench and lever are invariably on hand in any plant. The depth of the hole required is very much less than where a square tool with parallel edges is used for turning the screw.

These columns have already given us some kinks on which a screw clamp is useful and I believe that in connection with the above scheme a screw clamp could be used sometimes more conveniently than, and instead of, the lever. It would be advisable to select one having a depression in one of its bearing surfaces into which the tang of the tool could bear while in use. With both clamp and lever to hand, the one best adapted to the construction of the affected part and the neighboring members could be used.

Design and Constructional Features of Turbine Pumps *

By A. E L. Chorlton

There are milestones in the history of the evolution of the centrifugal pump, yet the wide extent of its successful application in turbine form is due to the overcoming of practical difficulties, both mechanical and hydraulic. This work has only been accomplished after prolonged experience, and success has only been reached after tedious and careful study and improvement of small details. In what follows, there is described and traced the development of some of the methods of successfully overcoming the difficulties referred to, while attention is drawn to points in design which are the result of the author's experience, the latter extending back to the infancy of the Turbine Pump Principle in engineering achievement.

THE turbine has become so highly successful as a pumping engine for duties of all description, that no apology is needed for offering a few practical notes on the design and construction of its detailed parts. It will be convenient to consider the subject under the headings of the various component parts of a pump. These are:—

I.—The stator, which consists of (I a) the casing or housing, and (I. b) the guide vanes or appliance for converting velocity energy into pressure energy.

II.—The impeller (considered separately).

III.—The balancing appliance — hydraulic or mechanical.

IV.—The rotor, considered as a whole, and including the spindle with its projecting sleeves, impellers, and in most cases the balancing appliance.

V.—The bed, and other details, bearings, stuffing boxes.

Of these components III., IV., and V., broadly speaking, are the factors governing reliability and resistance to wear, and I. b, and II. are those determining the efficiency.

It is proposed to deal at greater length with III. and IV., for the reason that they have probably been less discussed than the others, also their practical importance is of the greatest moment, but the whole subject cannot be adequately treated within the confines of a paper written during the present time. The chief points only of items I., II. and V. will be briefly reviewed:—

I.—The Casing

The individual impellers of a turbine-pump revolve in chambers or cells containing the outward flow guide-passages and the return conduits for the water; these chambers may be part of a whole in which the outer body is cast in one piece, or, an aggregation of a number of distinct cells without any outside envelope. There are, therefore, two main types:—

1—The Osborne-Reynolds or divided type, and sometimes called the "ring-type."

2—The Sulzer, integral or one-piece type, sometimes called the "cylindrical" type. Recent American practice provides a variation of this type with the housing in halves divided on the horizontal centre line.

The two main types are diagrammatically illustrated by Fig. 1 (a and b) and Fig. 2 (a and b), with variations in Figs. 3 and 4.

The Osborne-Reynolds pump and its evolution was dealt with by the author in collaboration with Dr. E. Hopkinson, in some detail in a paper read before the Institution of Mechanical Engineers in January, 1912. This type was followed at a later date by the integral one of Sulzer, which had, for a period, a considerable vogue. An examination of the present-day practice of various makers will prove, however, that the ring-type has ultimately proved the preferred one.

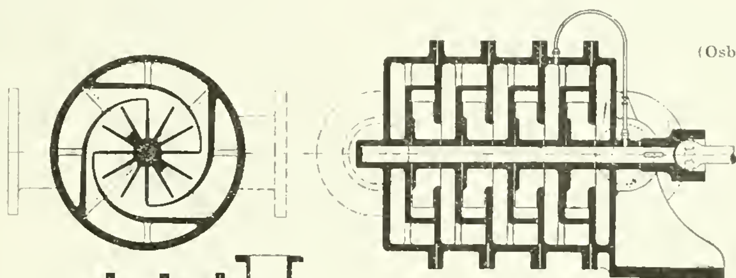

Fig. 1a. (Osborne-Reynolds).

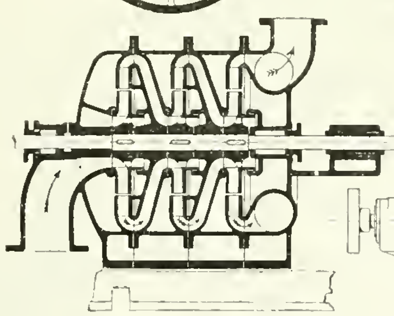

Fig. 1b. Ring Type Construction.

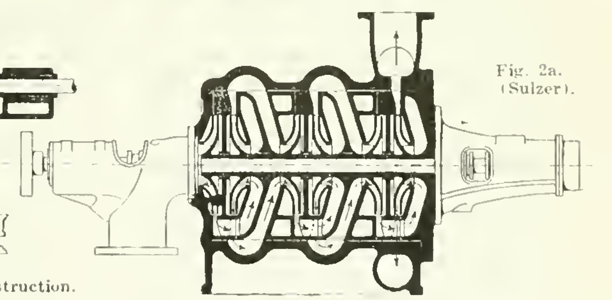

Fig. 2a. (Sulzer).

SECTIONS SHOWING TYPES OF TURBINE PUMP CASINGS.

The Reynolds pump has always used a separate cell for each impeller, and it is therefore correct to say that the ring-type of pump owes its inception to Great Britain. The continental form of the series turbine-pump is due to Sulzer (first pump 1896); in this type a monoblock housing was used for all the chambers or cells, the guide-vanes being inserted from the end.

Before dealing with either type or variations arising out of them, it is advantageous to consider the essential functions of the chamber or housing of a turbine-pump. Primarily, each cell consists of (1) the outward flow guide-passages in which the kinetic energy of discharge from the turbine-impeller is converted into static head, and (2) the return water-passages back to the centre for conduction to the next impeller; a complete housing is a collection of such cells.

Obviously, in the design, commercial considerations must have a material guidance on theoretical claims. Against the requirements for best theoretical conversion of kinetic energy must be matched the allowable limits of dimensions conformable with commercial possibilities, and, in the interests of efficiency, special attention must be paid to the arrangement and dimensions of the divergent channels or guide-passages. As is well known, the form for guide-passages is represented diagrammatically by Fig. 5, and this passage must be disposed in some form to lie conveniently in the desired casing. The general character will be either a simple outward flow type in one plane, Fig. 6, or a mixed type outward and axial in two planes, see Fig. 7 (a and b) and Fig. 8.

The divergent angle of guide-vane, Fig. 5, for best efficiency was shown by Professor Gibson to be 10° to 11°. In many cases such a small divergent angle leads to a large overall diameter guide-vane in order to give a sufficiently reduced speed of water to permit reversing its radial direction, and the result is a very heavy casing in consequence. For this reason divergent angles of 15° are

*From a paper read before the Institution of Mechanical Engineers.

commonly found in practice. Evidently a more efficient pump will sometimes be heavier and more expensive than one less efficient, and commercial considerations must provide the final deciding factor between efficiency and weight. There is, of course, a school of design which believes in dealing with a proportion of the velocity conversion in the wheel itself, thus leaving less to be dealt with in the guide-passage; the extent, however, to which this method can be used for weight saving is very small, if any. The various assemblies of passages may clearly be grouped into:

A—Tangential and radial with return radial (see Fig. 6 and Fig. 1, b).

B—Tangential and spiral (see Fig. 7 (a and b) and Fig. 8).

C—Combinations (see Figs. 9, 10 and 11).

The Osborne-Reynolds pump (1887 and 1875 type) employed an early form of the B assembly, and has adhered to this type up to the present day, various improvements being embodied from time to time, in some of which the author was concerned. On the Continent of Europe, Messrs. Sulzer introduced in 1896 design A, and the author believes they have made little departure from the type beyond a considerable simplification of their early arrangement of passages, Fig. 2 a Speaking generally, combination designs C are not so efficient as the simpler types A and B, owing probably to the hydraulic loss through changing the radial direction of the water at high speed.

From a works construction point of view, "ring casings," Fig. 1 (a and b), are the most economical, and in practice give high efficiency. In the form similar to that shown in Fig. 12, the author some years ago was able to mould and cast ring-casings without cores, machine moulding being adopted, and the cost per chamber coming out at a very low rate.

For "cylindrical" casings, Fig 2 (a and b), a complete pattern is required for each size and variation in number of chambers. Its accessibility, however, and ease of dismantling is sometimes considered to be greater than with the "ring" type, though this is, to a certain extent, a matter of opinion. A great drawback to casings containing separate cells is that, on account of the sliding fit between the intermediate pieces and casing, an unknown amount of leakage constantly takes place between the cells. With a "ring" type of pump, leakage is instantly detected and can be remedied. As a commercial proposition the author unhesitatingly favors the divided or "ring" type of casing, and when properly carried out, has met no difficulty with it in practice.

Fig. 3. Split cylindrical casing construction.

SECTIONS SHOWING TYPES OF TURBINE PUMP CASINGS.

Finish of Guide Passage Surfaces

Before leaving this part of the subject, a word about the finish of guide-passage surfaces is necessary. For best efficiency the throat of the passage at least, if not the entire passage, should be gun-metal or bronze, as iron does not preserve a sufficiently good surface for high velocity conditions. Common practice is to provide only three sides of the guide passage in bronze, Fig. 13, but this can only be defended on grounds of cheaper first cost. For best results a bronze-plate should be provided to box-in the passage, the plate being attached to the guide-vane casting or dowelled to the casing. Guide-vanes are sometimes cast completely boxed in, and this method necessitates hand finishing of the passage by file and scraper; open vanes, however, lend themselves better to cleaning out and accurately finishing either by hand or by machining. A good smooth surface is essential for the best results and will always justify the increased cost. The method adopted of securing guide-vanes from rotation and vibration must be a thoroughly sound one or trouble will result.

II.—Impellers

Impellers are either single entrant, or double entrant. The first is almost universally in use for multicellular pumps, and the second almost exclusively for single-chamber pumps; it is only proposed to deal with the single entrant form. Multicellular pumps use the single-eye wheel in three forms:—

(a)—Unbalanced, unequal side area, one rubbing shoulder, Fig. 14.

(b)—Unbalanced, equal side areas, two rubbing shoulders, Fig. 15.

(c)—Balanced—on paper, Figs. 16 and 17.

There are other types, mixed flow, radial and axial, etc., but these are not used to a sufficient extent to be worth including in this paper.

Type (a) may be said to be the one now generally used, that is, the preferable design.

Type (b) has certain advantages for machining, etc., but probably requires a stiffer shaft. Also, having no central sup-

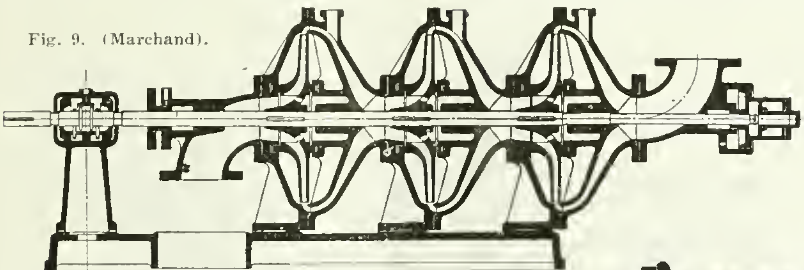
SECTIONS SHOWING TYPES OF TURBINE PUMP GUIDE VANES.

ports, it tends to rotate the suction water of the next impeller and may be attended by greater stage leakage due to the increased annular running clearance.

Type (c) has the paper advantage of being in balance; actually it is a poor approximation to a balance. Disturbing factors are set up by: differences in side pressure on the impeller due to differences in volume and surface-form of the water contained on the two sides of the impeller, Fig. 18; difference of quantitative leakage through the two shoulders; and high-pressure leakage into one side of the impeller from the stage above, and leakage from the other side of the impeller to next low pressure stage below. Therefore, in practice, it is necessary to provide an additional end balancing device of the hydraulic type, or a mechanically positioning fitting such as a thrust-collar or ball-bearing; a method, especially for mine usage, not to be recommended.

The internal design of all impellers is governed by the same controlling features:—

Fig. 9. (Marchand).



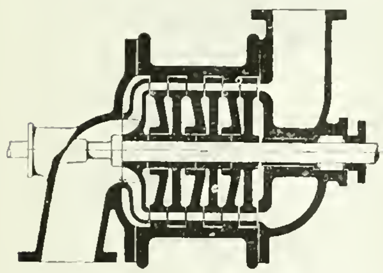


Fig. 11. Combined Axial and Spiral Flow.

SECTIONS OF TURBINE PUMPS SHOWING COMBINATION PASSAGE ASSEMBLIES.

1.—The entrance or inlet angle of vane.

2.—The delivery or exit angle of vane.

The entire design must, while based on these considerations, consult the convenience of the workshop to the utmost degree possible without departing from required dimensional accuracy. The standing difficulty with turbine-pumps, from the manufacturing point of view, is their constant variation to meet the infinite number of conditions of varying head, speed, and quantity encountered in practice. Whatever efforts are made, it seems impossible to keep to a small number of standard impellers if the highest efficiency is to be reasonably well reached each time. Efficiency, it should be noted, is really the prime factor in design and not apparent first cost, for the pump is very often driven by an electric motor of greater value. If, therefore, by the use of a pump of higher efficiency, a reduction is effected in the necessary power and size of motor, the combination will generally come out cheaper.

The maker who elects to change his impellers and diffusers to suit the demands of the inquiries as they come in, will obtain a higher percentage of orders than one who has standardized his, even though the latter may have reduced costs by making in large quantity. In considering if in any way it is possible to meet the designer's requirements without losing all the advantages of repetition manufacture, we may first take the inlet angle. This depends on the resultant of the (supposed) radial flow of the entering water and the peripheral speed of the inlet tip itself, and it usually varies between 15 degs. and 30 degs. If we select to use always 15 degs. we might suffer in some cases to the extent of 3 per cent. or 4 per cent. If we take two sizes, 15 degs. and 25 degs., and make a liberal provision of inlet width, or, as some designers phrase it, make an adequate allowance for "weir coefficient" at entrance, we shall only drop perhaps 1 per cent. in exceptional cases; so it seems possible to do something in the way of standardizing the inlet angle.

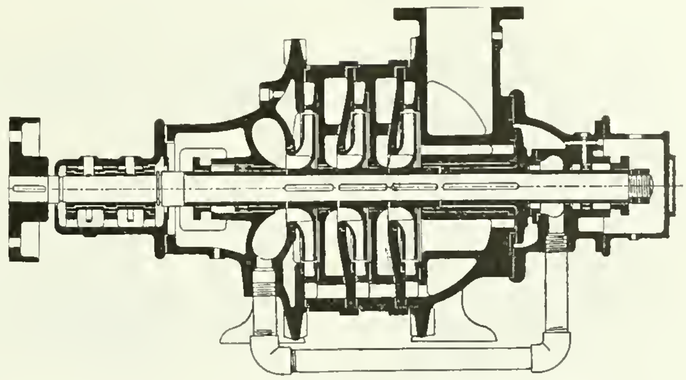

FIG. 12. MODERN FORM OF TURBINE PUMP (MATHER & PLATT).

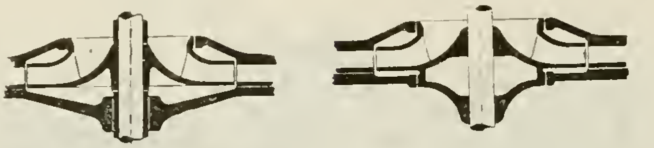
Current Ideas Concerning Inlet Angle

One might refer, in passing, to some of the current ideas concerning the inlet angle and the condition of the water at entry to the impeller. Some designers have maintained that very great accuracy of the inlet angle is vital to high efficiency, in spite of the fact that in the ordinary unobstructed eye it is impossible to say what the absolute velocity and direction of the incoming water is, and therefore, to estimate precisely what the correct inlet angle should be is impossible. Further, the behaviour of the incoming water varies with every rate of flow, and the only way to foretell its condition would be to insert inlet guide-vanes; this, however, in such experiments as the author is aware of, has proved an objectionable practice and only introduces further losses in the pump. Another school holds that it is an advantage purposely to introduce a forward whirl in the water at the eye with the object of helping the water into the impeller. If such an initial whirl is used, the work necessary to create it is necessarily done by the pump itself, and it is, therefore, questionable if this does not entirely overweigh any possible gain.

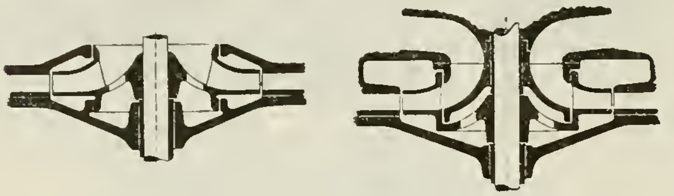
FIG. 13. (FARCOT).

The discharge angle depends on the resultant of the peripheral speed of the wheel and the radial out-flow, the variation of which is so great it seems impossible to devise any standardization. To meet quantity variation two widths of impeller may be used, and to meet required speeds of revolution it is usual to allow a small percentage variation in the impeller diameter to suit special demands; this latter, however, is conveniently done without pattern or casting alterations.

Unequal side area. One rubbing shoulder. Equal side areas. Two rubbing shoulder.



FIGS. 11 AND 15. IMPELLERS UNBALANCED.



FIGS. 16 AND 17. IMPELLERS BALANCED.

The foregoing considerations lead to the conclusion that nothing less than a special core-box will be required for each case, and it is quite usual to meet the difficulty in this way. Evidently, however, a most valuable appliance would be a special form of core-box, which in itself was more of a standard and could be adopted for manufacture in quantity; this result might be effected by fitting in vanes of a flexible nature, so that the necessary alteration and adjustment would not be great, and the whole outfit would come out cheaper than if a pattern-maker had to build a fresh box and fittings for each new demand. As the accuracy and smoothness of the impeller is of great importance, the author has always looked to machine moulding, and to a special machine like a wheel-moulding machine, for the purpose; he has not, however, as yet, arrived at the final design for such.

Impeller Surfaces

The surfaces of the impeller, both inside and out, play an important part in the efficiency of a turbine-pump. The smoother the outside surface the less the power lost in disk friction, and the less the power wasted in revolving idle "dead-water." An interesting point to note is that the greater the speed of revolution of the "dead-water" (that is, the greater the power absorbed in this way), the less the leakage from the periphery of the impeller; but a little consideration will show that greater overall economy is gained by reducing the wasted power in idle revolution to a minimum. As regards the internal smoothness of the passages of the impeller, it is usual practice to clean up the surfaces as well as possible with file and scraper. Impellers have been built up with one loose side so as to permit of machining or more effectively cleaning the interior; and it is evident that with individual impellers producing high heads the results would well repay the extra cost. Objections to this practice are the difficulty of making attachment of the two parts and the extra weight necessary to provide attachments.

III.—Balancing Appliance

The experienced designer knows, from practical knowledge, that even if a group of impellers, or even a single impeller, is theoretically balanced by equivalent areas subject to pressure, it will not in actual practice be free from all end thrust. Apart from variable leakage at the two sides of an impeller, which, by the way, is the principal cause of end thrust, we often have variable side surface both of the impeller and the cell chamber. If the conditions of capacity or surface of the two clearance-chambers vary, the resulting pressures will vary and an axial thrust is set up. Professor Gibson has investigated the effects on efficiency (power lost) due to varying the side clearance of the impeller, and he took readings of circumferential pressures set up by revolving disks, but he apparently did not plot out the resultant effect in end-pressure. This interesting problem is discussed in a paper by F. Zur Nedden, where use is made of the results from both Professor Gibson's and Professor Unwin's revolving disk experiments. The general effect of the gyratory pressures set up is indicated in Fig. 18. It is seen that the speed of the revolving "dead" water at the two impeller sides sets up pressure in opposition to the leakage pressure from the impeller-tip, as already pointed out; the faster the water revolves the greater the resistance to leakage, and the less the resultant pressure due to that leakage. It can readily be seen, therefore, that the effect of the chamber at one side of a wheel having greater capacity than the other, or having more obstructions in the way of ribs, pockets, or exceptional roughness, etc., plays some part in the determination of end-thrust.

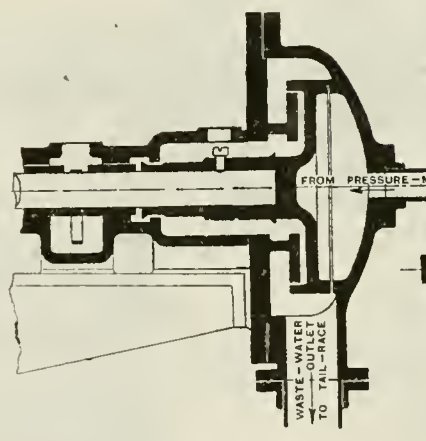


FIG. 19. HYDRAULIC AXIAL BALANCING DEVICE (FRANCIS).

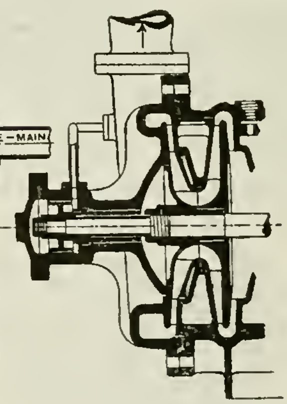

FIG. 20. PUMP (RATEAU) SHOWING HYDRAULIC COMPENSATOR.

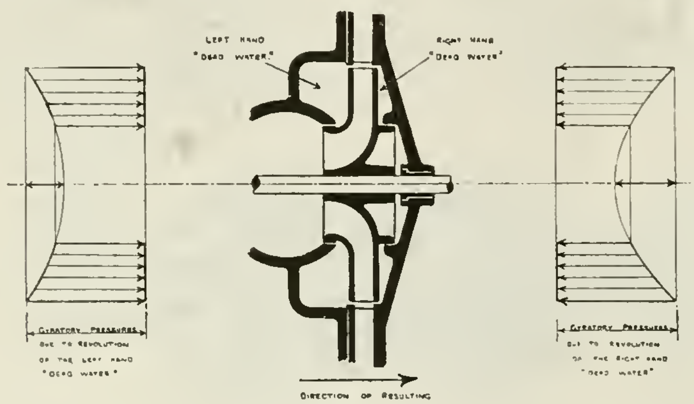

FIG. 18. EFFECTS OF GYRATORY PRESSURE ON END THRUST.

All the earlier turbine-pumps employed some form of thrust bearing, either of the collar or the ball type, to keep the impellers in correct alignment with the guide passages, and it was not until much trouble had been experienced with these that hydraulic control was ultimately adopted. Experience showed that much higher end pressures were set up than were ever anticipated, but for a period mechanical devices were persisted in, improvements being made attempting to withstand the excessive loads, and scant notice, it would appear, being taken of water-turbine practice where for many years it had been the custom to relieve axial thrust hydraulically. Fig. 19 illustrates an hydraulic balancing device in use on Francis turbines, and which, if properly proportioned, is automatic, and thus embodies all the essential points of many present turbine-pump balancers. One should bear in mind that the relation between the calculable axial thrust and the thrust realized in a water-turbine is much closer than in a centrifugal pump of the multi-stage type, the reason of this being that the disturbing factor in a high-lift pump is the leakage from stage to stage.

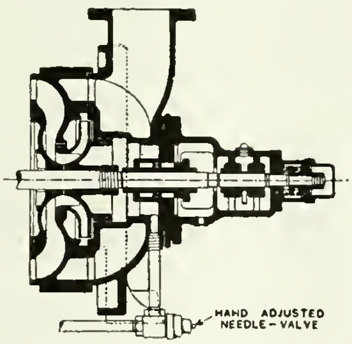

FIG. 21. HAND ADJUSTED BALANCER.

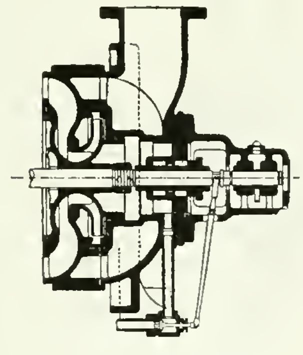

FIG. 22. MECHANICALLY ADJUSTED BALANCER.

The well-known application of turbine-pumps to high lifts by Messrs. Sulzer at Horcajo Mines in 1898, was carried out with back-to-back impellers, and a ball thrust-bearing was provided to take the end-thrust (in one direction only), which is inseparable from this arrangement of impellers. In 1901, Professor Rateau was manufacturing pumps with end-thrust approximately eliminated hydraulically by his well known method of shroud reduction, and provided with a balancing piston, Fig. 20. This method was not automatic, and the pressure on the piston could only be adjusted by means of a hand-operated throttle-valve. However, this was the first step, and the automatic control of the necessary pressure on the balancing device and determined by the end movement of the spindle followed as a matter of course. The development of the differential type of balancer carried out under the author's direction in 1913, extended over several years, progressing step by step from a hand-adjusted needle-valve, Fig. 21, regulated to produce the required balancing pressure, to a mechanically-operated needle-valve, Fig. 22, actuated by the axial movement of the spindle, and then through several forms of rotating throttle-valve disposed on the spindle itself and actuated by the same means. Further reference to the final balancing appliance (diagrammatically shown in Fig. 23) will be made shortly.

In 1906, Messrs. Sulzer brought out their device for relieving thrust shown in Fig. 24, and the principle used has been followed by many other makers and introduced with many variations. The action of the Sulzer device is simple; it comprises a single plate with a throttling device, through which the pressure water has access to the plate. The area of the plate is sufficient when acted on by a somewhat throttled delivery-pressure to overcome the tendency of the rotor to travel in the opposite direction. As the pressure gradually rises before the plate, its increased power carries the rotor to the right until further motion is arrested by the escape of the increased pressure through a widening annular space between the plate and its facing seat. An ultimate running position is reached when the leakage through the clearance between valve and seat is sufficient to maintain a pressure at the back of the plate, equal to the set of the rotor in the opposite direction. It will be seen that the balance is quite automatic in its control, end-movement in either direction taking place until stability is reached.

Without going further into the detailed evolution of automatic control of the hydraulic end-balance of the turbine, it is sufficient to say that the devices adopted resolve themselves into two basic forms:—

(a) Single acting (simple), of which the Sulzer, Fig. 24, is the general type.

(b) Double acting (differential), of which Fig. 23 is the type, and Fig. 13 a modification.

Other single-plate forms are shown in Figs. 25 and 26. In the first of these the throttling agent, a small nipple, is removed to the discharge side of the plate, thus giving, in a measure, a double action to the plate; the quick action and limited travel due to the second face of the differential type is not obtained, however, and there is a possible disadvantage in the small aperture when dealing with impure water. The second example combines some of the points of both forms of balancer, but as the pressure in the spent-water chamber is always augmented by high-pressure leakage into the low-pressure side of the plate, the device is, obviously, relatively extravagant in leakage water, and must therefore be considered inefficient.

The general effect of wear on single-plate balancers is increased leakage, the outcome of which is further end-movement in one direction until finally the impeller discharges do not match their guide-vane entrances, but become off-set. This tendency in hydraulic balancers led the author to devise form "b," or the double-action control with which such difficulties are overcome.

Fig. 23 (also in Fig. 12), finally shows the present standard double-plate or compound differential balance arrangement. The balance-piston and regulating valve are combined, and form a balance-disk with two active throttling surfaces floating between two fixed seatings with a minimum clearance. All the working faces are arranged vertically so as to be independent of possible vibrations of the rotary system. The pressure-water, escaping from the rim of the last impeller, passes through the holes h, into the pressure chamber m, from which it escapes along the throttling surface of the balance-valve into the regulating pressure-chamber k, and from there, past the

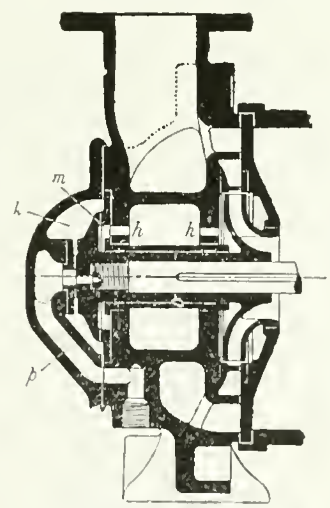

FIG. 23. DIFFERENTIAL HYDRAULIC BALANCER.

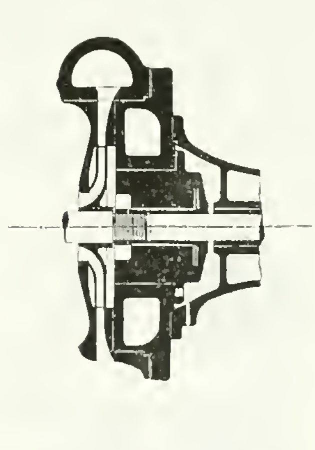

FIG. 24. SINGLE PLATE BALANCER (SULZER).

small throttling surface into the escape-pipe p, leading preferably to an open drain, or, back into the suction-chamber of the pump. The double-plate balance appears to be the most sensitive automatic balancing device in practical use, for by it, closing up of the plate on the

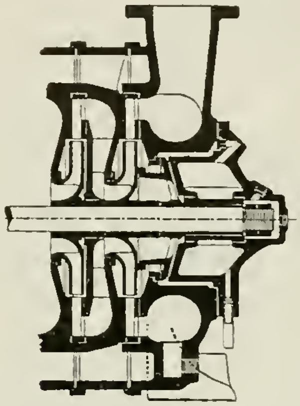

FIG. 25. (MILLINGTON

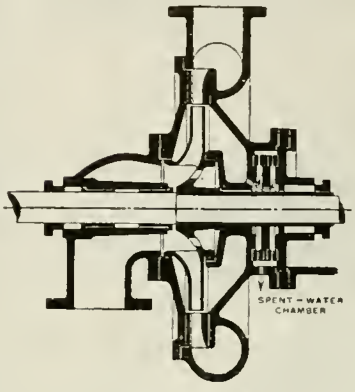

FIG. 26. (SCHEURMANN).

SINGLE PLATE BALANCERS.

large throttling face causes an opening out on the small one, thus multiplying the balancing effect; a movement of a thousandth part, or so, of an inch being all that is required to counterbalance the most extreme and sudden changes of the hydraulic equilibrium of the pump. The other and most important feature of this auto-plate balance is that it always maintains the central position of the impellers, even if the throttling surfaces become worn, as is invariably the case when pumps are working on gritty water.

A continental form arising out of this type is shown in Fig. 27, and it is obvious that the same remarks concerning extravagance in leakage water apply to this example as to Fig. 26. The arrangement of the balancer at the end of the spindle outside the external bearings is not a good one, for the reason that a high-pressure gland at the delivery end of the pump is still required, and an additional gland also for the balancer-housing. A single-plate balance made by the same firm as the above is shown in Fig.

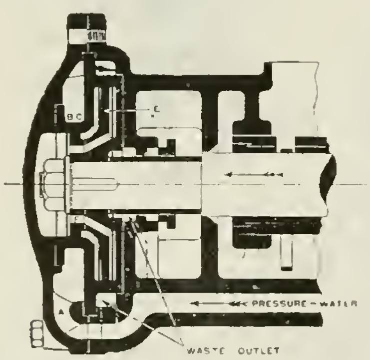

FIG. 27. DIFFERENTIAL.

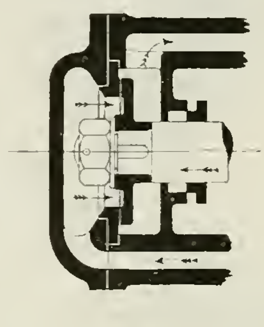

FIG. 28. SINGLE PLATE.

CONTINENTAL HYDRAULIC BALANCERS.

28, and this, too, is open to the same objection as regards disposition on the spindle.

It is usual to make hydraulic balancers with renewable faces at the points of close-running, so that the appliance can be readily repaired after wear has taken place. As regards the best material to be used for the renewable part, some considerable experience is needed before a decision can be made. Gun-metal was probably the first material to be used, but cast-iron, cast-steel, and hard bronze have all been tried, the present practice usually being to fit hard bronze. The ideal material is one which is hard and "short," and has a very low coefficient of friction when working in water; a material which "drags" is quite unsuitable, and apparently an incorrodible iron, one containing a high percentage of silicon or a nickel steel, seems to best fit the requirements. Non-metallic substances, such as red-fibre, woodite or dexine, have been considered, but any material which becomes slightly absorbent after long immersion is useless.

Sometimes difficulty is experienced in starting up large turbine pumps on account of the large diameter balance-rings being held together in metallic contact instead of being apart in their usual running position; the result is an abnormally high starting torque for the motor and probable damage to the faces of the balancing device. When a turbine-pump with differential balancer is "stopped," the rotor will always take up a position with the balancing faces apart if the waste-water outlet (Fig. 29), is taken to an open drain; however, if the spent water is led back to the suction pipe of the pump and a foot-valve is provided at the end of the suction-pipe, the whole rotor is forced towards the suction-end of the pump as soon as the foot-valve closes and the head pressure comes on. The reason for this is that the area of the balances on the outlet side is greater than on the inlet side by an amount equal to the diameter of the spindle. For this reason, the waste water from a balancer should not be connected to the suction-pipe of a pump, or means should be taken in the pump to equalize the areas subject to the static hydraulic pressure (Fig. 12).

IV.—The Rotor

As is well known, the internal design of a multi-stage turbine-pump involves a rotor comprising a number of impellers keyed on to a shaft, the shoulders or bosses of which abut on each other and are secured and maintained together by double nuts or the like at, or near, the ends of the shaft. Such portions of the shaft as are not covered by the impellers, but are subject to the action of the pumped liquid, are protected by sleeves which fit up to the impeller bosses and thus make a complete sheath outside the shaft itself, Fig. 1 (b), and Fig. 2 (a and b), etc.

This rotor revolves within the guide-chamber and housing, each impeller running at some points in the closest proximity to the partitions dividing the pressure-stages and return-guides.

These so-called running joints or neck-rings must be so maintained by design and construction as to secure in continued service the smallest possible hydraulic leakage-back from stage to stage, or mechanical loss by rubbing friction, both of which effect the efficiency and wear and tear of the pump. As a question of practical importance, the design of this combination probably follows next to that of the successful automatic hydraulic balancing of the axial end-thrust. We have in it the question of the deflection of the pump-shaft; the reinforcing effect of the surrounding impellers; the support afforded by the bushes, if any, between each stage, and the loss by bush friction (wear); the form of neck ring to reduce leakage; and the effect of keyways and keys, etc., all independent of each other and affecting the whole.

The ideal condition is that of a rotor supported in lubricated bearings with a shaft of such sufficient stiffness between supports that the deflection, under all possible running conditions, is less than the clearance allowed at the neck rings and intermediate bushes, so that no contact takes place between the rotating and the fixed members, this clearance at the neck-rings and intermediate bushes being kept down to the smallest possible limit. It will be seen that it is impossible to present mathematically, the exact conditions with such a number of incalculable factors to take into account.

For instance, it may be thought that a not inconsiderable reinforcing effect is obtained by the combination of the impellers outside the shaft as a whole. In practice, however, it is not advisable to lock up the impellers together shoulder to shoulder against each other by the end-nuts in order to get the advantage of the reinforcing effect; because, due to, amongst other things, the slight inaccuracies of manufacture in squaring the shoulders of the impellers, sleeves, etc., the result would be to throw the combination out of truth, that is, to distort the shaft.

It might be contended that this need not be so, but even then provision must be made for dismantling in a mine or similar place, with its obvious attendant disadvantages, and the possibility of rough treatment taking place; furthermore, as a safeguard against heating up and consequent expansion of the outside combination (bronze) against the internal (steel) shaft due to accidental contact with the intermediate bushes, running, perhaps, when the pump is empty, suitable expansion should be allowed for, and the impellers, to ensure this, must not be locked tight against each other.

The supporting effect of the bushes on the shaft, in passing through the diaphragm intermediate between the impellers, is very difficult to exactly allow for; it may be that the bushes will decrease the deflection of the shaft by a material amount, but it must not be assumed for one moment that they are bearings of such a nature as lubricated bearings. Intermediate bushes can only, in some cases, be considered as water-lubricated supports which will act as such so long as a certain low surface pressure on them is not exceeded; if too great pressure comes on, heating takes place on account of the high speed of rotation. The effect of wear has also to be taken into account for the hydraulic pressures at the two ends of these bushes are different and there is, therefore, always a flow taking place through them, carrying with it any sedimentary or foreign cutting matter which may be in the water. This state of things causes the supports to wear more or less rapidly so as to become almost useless, the pump eventually arriving at a condition worse than if a suitable clearance had been allowed at the first.

The author believes that too much use is made of these intermediate supports in turbine-pump design. It is found in practice that an internal bearing to be successful must have the same water pressure at both ends, and must be properly lubricated with good grease, it then gives excellent results. We are thus left with the fact that we are practically dependent on the shaft itself for the necessary strength and stiffness to allow of fine internal clearance, and the importance of a good design which will economically give the minimum deflection of spindle at once becomes apparent. The factors affecting the deflection of a turbine-pump spindle are:—

Static

(a)—The weight of spindle and distribution of diameter change;

(b)—The weight and distribution of impellers, balancer, and parts;

(c)—The number and span of supporting bearings; and

Dynamic

(d)—In the dynamic condition, other incalculable forces entering into the account, such as, centrifugal forces due to the out-of-balance masses, and finally certain hydraulic disturbances.

(a)—Should be as light as possible consistent with the necessary stiffness; in common practice spindles are practically parallel the whole length.

(b)—Impellers and balancer should be grouped together as closely as possible, only allowing sufficient space for the water passages between the stages; also, the entire weight should be brought as close to the supporting bearings as possible.

(c)—The span of supporting bearings plays such an extremely important part in the durability of the pump; in the possibility and preservation of fine clearances; in the whirling of the shaft, and in the determination of the most economical size of spindle, that special notice will be taken of it.

(d)—A loaded shaft supported horizontally between two bearings will "sag," and when rotated must suffer bending at every revolution. Also, there are bound to be certain out-of-balance masses in the rotor due to keys, heterogeneous composition of material, and the unavoidable variation in thickness of castings, etc. In addition, a shaft has vibrational periods due to its length and diameter, the whole question of vibration being intensely complicated by the loading and supports.

In addition to the disturbing factors mentioned above, vibrations are set up from the reaction of the impeller vane passing the guide vane. It is usual to reduce the intensity of this disturbance by arranging an odd number of vanes in the impeller relative to the guide vane, and by setting successive impellers on the shaft in such a way that the point of passing-vanes is progressive throughout the series, i.e., a "lead" is given. The resultant of these arrangements is to produce a vibrating influence, which may be torsional or combined torsional and transverse, of very high frequency and enfeebled intensity and which, when properly carried out, is free from practical disadvantage. The damping effect of the water film in neck bushes is appreciable in overcoming slight vibrations, as is conclusively shown by the different behaviour of a spindle when running a pump dry and when running it filled with water. In order for a shaft to oscillate, it must force liquid out of one side of a neck-ring, and the retardation offered by this action has a noticeable effect. For this reason, quite apart from the lubricating effect gained, it is always a wise precaution to fill a pump with water before running it, otherwise if the shaft is not a stiff one seizing-up will probably occur. The remedy for spindle vibration due to any cause whatever is always a stiff shaft.

The whole matter of whirling shafts has been examined by several investigators, prominent among whom is Professor Dunkerley, but it is not proposed to discuss the matter further than to refer to the general proportions affecting the critical speeding of whirling. We find that the length (l) of span of bearings, and the diameter (d) of the spindle have an effect varying as:—

$$\frac{d^4}{l^3}$$

Turbine-pumps do not usually run at speeds approaching the critical speed, but the maximum safe speed for any rotor will bear a direct relation to the critical speed, in the sense that it will be an equal factor for equal safety. The above relation shows then, that for a fixed critical speed a reduction in the span of the bearings results in a material reduction in the necessary shaft diameter. The effect of axial thrust—always present in a turbine-pump—in lowering the critical speed of a spindle should always be borne in mind

SPAN OF BEARINGS THREE ARRANGEMENTS.

High Pressure Air Compressor Design and Application*

By Joseph M. Ford

Compressed air at high pressure is becoming an increasingly important medium in modern engineering practice and in naval warfare. The accompanying paper deals with the machines which produce high pressure air, leaving on one side the question of power transmission by compressed air. In passing, the principal advantages of this system are referred to, and will be seen to be of considerable value. They consist of the facility with which energy can be stored; the unlimited rate at which accumulated energy may be converted into useful work; and, apart from loss of efficiency, leakage cannot cause any awkward consequences.

THROTTLING

In a compressor which has its suction throttled, the volumes dealt with by the stages are of course reduced, which naturally involves a decrease in stage pressures. In a compressor with no cylinder clearances there would be no limit to the possible compression ratio in any cylinder; that is, the initial pressure in, say, the high-pressure cylinder could be very low and yet the machine would deliver air. In a cylinder with a large clearance, however, there is obviously a definite limit to the ratio of compression if air is to be delivered. If this ratio were exceeded, the air would simply be compressed into the clearance space and re-expanded. In other words, in order that the compressor shall deliver air, the intermediate-pressure delivery pressure must attain a definite figure, so that the total work is still divided between the stages, although not necessarily in correct proportion. The theoretical minimum initial pressure from which a cylinder can compress and just deliver (assuming no leakage) can be obtained from the equation:—

$$c\left[\left(\frac{P_1}{P_2}\right)^{\frac{1}{n}}-1\right]=1$$

where

c is the clearance ratio,

P_1 is the delivery pressure (lb. per sq. in. absolute),

P_2 is the minimum initial pressure (lb. per sq. in. absolute),

and

n is the exponent in PV^n=constant.

The above expression shows that P_2 increases as c is increased, and that with large clearances the compression ratio in any stage when the compressor is running throttled can be kept within limits, whereas in a machine having very small clearances the high-pressure compression ratio, with excessive throttling, might reach an abnormal figure, resulting in excessive temperatures in that cylinder. The foregoing would tend to show that a compressor with good clearance volumes is preferable to one with small clearances, and for some Diesel engines — especially those of the marine type, where the conditions under which the compressor works may vary between fairly wide limits—this is the case.

As previously mentioned, clearance results in a reduction in the effective capacity of a cylinder, so that larger cylinders must be fitted than would be necessary with no clearance volume. The direct result is an increase in the piston loads. For example, a compressor of 300 cub. ft. per minute displacement at 350 r.p.m., having stage pressures of 45 and 300 lb. per square inch, when working at 900 lb. per square inch delivery pressure, and cylinder clearances for low pressure, intermediate pressure and high pressure of 4, 5 and 10 per cent. respectively, has a maximum air load on the high-pressure piston of about 7,900 lb., whilst the maximum intermediate pressure piston load is 14,300 lb. In a similar machine having, however, low pressure, intermediate pressure and high pressure clearances of 4, 15 and 30 per cent. respectively, the high-pressure piston load is increased to 12,100 lb. and the intermediate pressure load to 22,800 lb. Figs. 12 and 13 give for various clearance ratios the maximum piston loads for compressors of the above capacity and stage pressures.

and 13. Inspection of the diagrams superimposed shows that as the clearance is increased the commencement of delivery and the commencement of suction, in both the intermediate-pressure and high-pressure cylinders, occur later in the stroke. With a large clearance, therefore, the maximum cylinder load is not attained until the crank is at a somewhat smaller angle from the dead centre than would be the case in a machine with no clearances, due to the fact that the actual compression takes place during a longer portion of the stroke, and further, the re-expansion of the greater volume of clearance air occupies a larger portion of the stroke, so that the pressure acting on the piston does work on the crank through a greater angle than it would were the cylinder clearances small. The crosshead load (neglecting inertia and weights of parts) at any point in the stroke, for the particular type of machine under consideration, is the difference between the intermediate-pressure piston load acting upwards and the low-pressure and high-pressure loads acting downwards, so that with the increased clearances the greater loads in the high-

*Part II. of a paper read before the Greenock (Scotland) Association of Shipbuilders and Engineers.

pressure and intermediate-pressure cylinders tend to balance one another to some extent. The result of this is that although the actual piston loads are considerably increased with large clearances, yet the maximum turning moment is augmented to a much less extent.

Fig. 15 gives the turning moment diagrams for two of the three compressors previously mentioned, namely, that with the 10 per cent. high-pressure clearance and that with the 30 per cent. high-pressure clearance. It will be seen that the maximum value occurs in this case when the crank is about 65 deg. from top centre. The comparatively small increase in maximum turning moment with the larger clearance, compared with the increase in the actual piston loads, is to be noted. The effect of the increased clearance volumes on the crank angles at which the various events of the cycle occur is also clearly seen.

Fixing of Stage Proportions

When a machine is required to deliver a given quantity of air at a given pressure, one of the first decisions concerns the number of stages in which the compression should be effected. The main factors are: the initial cost of the machine, reliability and economy in operation, and safety in operation.

The initial outlay increases as the stages are multiplied. With a small machine the gain in economy and safety in operation due to increasing the number of stages is of less importance than in a large one. Cooling will be more effective due to the smaller cylinders, and the castings will probably be more reliable, thus lessening the chances of breakdowns. In addition, piston leakage in a small two-stage machine will probably be much less than in a three-stage machine of similar capacity, because in the former there will only be leakage past two sets of rings, whereas in the latter there are three sets. Moreover, the high-pressure piston in the two-stage compressor will obviously be larger than that of the three-stage one, so that the piston rings are much more likely to be airtight. It is a recognized fact that in practice small rings, in spite of the smaller circumference, are more difficult to make tight than large ones.

The necessity for reliability demands, for reasons previously mentioned, that the temperatures in the cylinders be kept as low as possible, which in large machines, where the cooling is comparatively poor, demands division of the compression into several stages.

An important point in the computation of stage proportions is to arrange as far as possible for equal temperatures in each stage, for then the highest temperature is a minimum. Theoretically, this can be attained by dividing the work equally between the stages—which also results in the minimum of work required per unit of air compressed. In practice this is only true when the cooling effect is the same for all stages and the intercooling perfect.

Fig. 16 shows the theoretical theta-phi diagram for a three-stage compressor delivering air at 900 lb. per square inch gauge pressure. With equal division of work between the stages and intercooling down to the initial atmospheric temperature, the heat equivalent of the work required per lb. of air is represented by the area under ABHMPGR down to the line of absolute zero temperature (diagonal shading). The cooling effect is assumed to be the same for all stages, and as a result it will be seen that the miximum temperatures attained are the same for each stage of compression., 260 deg. F. The distance a, b, and c are, of course, equal, since the compression ratios of the stages are identical.

Supposing that, owing to restricted water supply, climatic conditions, or circumstances connected with the design of the machine, it is found that in the first stage intercooler the air can only be reduced in temperature to 90 deg., and in the second stage intercooler to 120 deg., then the diagram is modified as shown by the dotted lines. The heat equivalent of the work required per lb. of air will then be represented by the area under ADJLOGR down to the line of absolute zero temperature, the excess over the previous case being represented by the horizontally shaded portions. The temperatures attained in the stages are no longer equal, but increase towards the final delivery. In this case they are: low pressure = 260 deg., intermediate pressure = 300 deg., high pressure = 340 deg. The compression ratios of the stages are, however, still equal.

With the poor intercooling, even, the maximum temperature of the cycle can be reduced by changing the distribution of work between the stages.

If the compression ratios in the various stages are made in the proportion x : y : z (see Fig. 16), then the stage temperatures will be the same, and consequently a minimum, although the intercooling is bad and the work distribution unequal.

The modification to the temperature-entropy diagram for these latter conditions is indicated by the chain-dotted lines, and the work in this case is the area under ACFKNER down to the absolute zero of temperature line. This is found to be slightly less than that required for the previous case, in which the compression ratios were equal. In some cases, therefore, better results are obtained from an unequal distribution of work than would be the case were each stage given an equal share, and also it may be pointed out that probably more valve trouble results from excessive temperature than from any other cause.

The design of certain machines is such that the cooling in some stages is likely to be very much better than that in others, in which case the work in the well cooled stages can be increased, and thereby relieve to some extent the stages with inefficient cooling.

Fig. 17 shows approximately the entropy diagram which would be obtained from a test on one of the machines previously referred to, namely, that with the low-pressure clearance 4 per cent., intermediate-pressure 15 per cent., and high-pressure 30 per cent. of the piston displacement.

It is not proposed to enter into the question of the application of the theta-phi diagram to air compression. The peculiar shape of the lines representing the change from the initial condition to the final condition at end of compression is due to the transfer of heat from the cylinder walls after compression has commenced and to the heat added to the air as a result of piston friction. The deviation to the right of the vertical indicates that the air temperature is rising even faster than with adiabatic compression as a result of the addition of the said heat. Later on in the stroke cooling sets in and the compression becomes further removed from the adiabatic, shown by the line bending over to the left.

The atmospheric temperature is assumed to be 60 deg. F. The point "X" represents the initial condition of the air in the low-pressure cylinder just before compression begins, and it will be observed that the temperature has been increased by the amount delta t_1 (in this case 20 deg.), the increase being due to the fact that the air on its way to the cylinder has become heated through contact with hot valves, etc. In this particular case, with a mechanically controlled suction valve, the initial pressure is seen to be very slightly above 14.7 lb per square inch, due to the inertia of the moving column of air in the suction pipe.

The first stage compression is carried to 59.7 lb. per square inch absolute and the temperature rises to 320 deg. F., the large rise being due to the fact that cooling is rather bad in this stage, partly as a result of a large portion of the "cover" being occupied by the high-pressure cylinder and the rest by large delivery valves, so that cooling cannot well be applied to this part. From the diagram it will be seen that the resultant compression is almost adiabatic.

After the first stage of compression the air is cooled in the intercooler to 80 deg. F., but on entering the second stage cylinder it again increases in temperature delta t_2 due to the hot piston, passages, etc., and also as a result of mixing with the re-expanded clearance air. The restriction in the intercooler tubes and in the valves results in a pressure drop, so that the initial second stage pressure is somewhat lower than the low pressure delivery pressure.

The total effect, then, of the above is that the initial condition in the second stage cylinder is represented by point "Y" in stead of point "J," as would be expected.

It is assumed that the large clearance space in the intermediate-pressure cylinder is well cooled, and this, together with the good packeting effect, results in the compression being further removed from the adiabatic than it is in the low-pressure cylinder, so that in spite of the considerably greater share of the work done by the intermediate-pressure, the temperature of compression is not very much in excess of that in the previous stage. A similar sequence of events takes place in the high-pressure cylinder, where, again, owing to the large well-cooled clearance, compression is within the adiabatic. This, together with the fact that the high-pressure stage has the smallest share of the work to do, results in the comparatively low final temperature of 240 deg. F.

Even with a poor distribution of work, as in this case, the temperatures need not necessarily be excessive. There are, however, other aspects of the problem of determining stage proportions. Consider the case of a high-speed Diesel engine compressor, where it is desirable that the balance and twisting moment diagram of the machine should be as good as practicable, in order as far as possible to eliminate vibration.

With a machine of a certain type, it will be obvious that the crosshead load at the top centre will be due to both the low-pressure and high-pressure delivery pressures on their respective pistons, whilst at the bottom centre the load is only that due to the intermediate-pressure pressure. The maximum upwards load is then about twice the maximum downwards load, which would not conduce to the best running.

There are two ways of bettering conditions, one of which is to retain the stage pressures and adjust the intermediate pressure clearance until the load approximates to that desired (see Figs. 12 and 13), and the other is to choose the stage pressures so that the upload is reduced and the down load increased. Increased down loads necessitate larger connecting rod bolts, which in some cases, on account of the restricted space available, might not be easily accommodated.

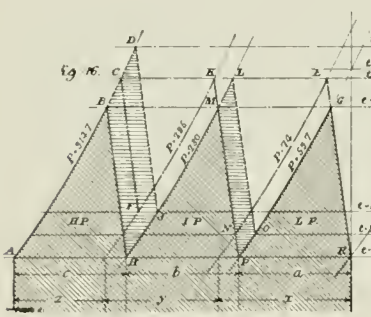

FIG. 16.

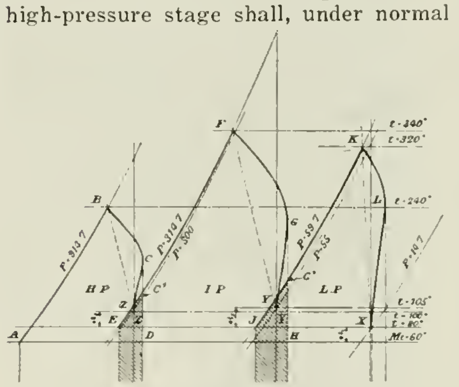

FIG. 18.

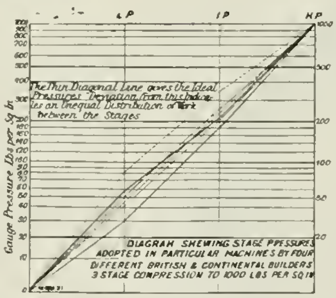

FIG. 17.

This chart may also be used to determine the ideal stage pressure (i.e. equal compressions per stage for compression to pressures up to 1,000 lbs. per sq. inch in 2 or 3 stages. For 3 stages of compression a line from the zero point to the intersection of the delivery pressure line and vertical H.P. cuts the other verticals in the ideal pressures. Example:—3-stage compression to 500 lbs. per sq. inch gives—L.P. pressure 33 lbs. per sq. inch, and I.P. pressure = 142 lbs. per sq. inch gauge. For 2-stage compression join zero point to intersection of delivery pressure line and vertical I.P. The L.P. pressure can then be read off as before.

Provision for Variable Delivery Pressures and Volumes

Another consideration when fixing stage proportions is the possibility of the machine being run at delivery pressures higher than normal.

In the remarks on clearance this question was mentioned, and the advantages of large clearances in this connection were enumerated.

The loads to which large clearances give rise (Figs. 12 and 13) might be inadmissible for various reasons, whilst the increased cost due to the larger cylinders might be a disadvantage, so that the constant proportional division of work between the stages, almost always approximately possible of attainment by choosing suitable clearances, would not in this case be secured.

If the machine runs at a pressure above its normal the division of work will be upset, and the high-pressure stage will take a considerably increased share of the total load, which may result, among other things, in an undue rise of final delivery temperature. If this latter is reasonably low when the machine is working at normal pressure, the rise due to the increased pressure will not be of such great consequence. To meet these conditions it is usual to arrange that the high-pressure stage shall, under normal conditions, take rather less than its proper share of the total work. The temperature in the other stages will be somewhat increased, but the rise in these temperatures due to the small increase in pressures as a result of the greater delivery pressure is inconsidearble.

If the machine has to run throttled in order to reduce the volume delivered, then it is again desirable, if possible, to arrange that the high-pressure stage shall under normal conditions take the smallest share of the work, since throttling reduces the stage pressures without altering the delivery pressure, thereby resulting in an increased high-pressure delivery temperature.

The importance of keeping the high-pressure temperatures low may again be emphasized. Burning and explosion of the lubricating oil here is of great violence when it does occur, which happily is very rare, due, among other things, to the attention given to the selection of the oil itself.

Volumetric Efficiency

One other point which arises in connection with the determination of stage proportions is the question of the volumetric efficiency of the low-pressure cylinder. If the low pressure stage is given a large share of the work, the effective capacity of the machine will be less than it would be with a lower first stage delivery pressure for reasons explained in the notes on the effect of clearance.

From the above it will be seen that multistage compressor design is to a large extent a matter of compromise. Each case should be treated by itself according to the duty of the machine and conditions under which it is to be run, and the best combination under the circumstances of loads, balance, and temperatures should be found, whilst the behaviour when throttler or running at various pressures must also be considered.

The question of cost should not be forgotten, for in some cases the advantages gained by, say, adding clearance, and thereby increasing cylinder sizes, may not warrant the additional expenditure.

Cylinder Proportions

Fig. 18 shows the stage pressures adopted in some of the very latest three-stage compressors for Diesel engines, by four different British and Continental builders, and bears out the remarks regarding the compromise in design of compressor.

Having decided on the stage pressures and cylinder clearance ratios, the actual determination of main dimensions is relatively simple.

When fixing the cylinder sizes, the low-pressure cylinder is settled first, as in a steam engine. A low-pressure delivery pressure is assumed—basing the assumption on previous practice if available—and from this pressure and the clearance volume in the cylinder (depending largely upon the type of valves used) the indicated volumetric efficiency is calculated. The dimensions of the cylinder are chosen such that, after the clearance air has re-expanded, the cylinder can draw in the required amount of air, plus an allowance for leakage through the compressor. Regard should also be paid to the fact that the air on its way to the cylinder, through contact with hot valves, passages, etc., becomes heated—which reduces the actual weight of air dealt with.

Where the workmanship is of the first order, about 85 to 90 per cent. of the air actually taken into the compressor will be delivered when compressing to 1,000 lb. per square inch in three stages.

The second stage cylinder is proportioned so that after its clearance air has expanded it can contain the whole of the air delivered by the low pressure at the low-pressure delivery pressure, and at the temperature resultant upon the mixing of the incoming and the clearance air. Attention should again be given to the effect of the hot cylinder cover, piston, etc. The other stages are similarly treated.

Experience is an important factor in the settling of cylinder proportions, as in the higher stages, at any rate, it is essential that allowance be made for leakage. For example, in a four-stage machine compressing to 3,500 lb. per square inch, possibly not more than 80 per cent. of the air taken in ever reaches the high-pressure cylinder. If this cylinder is made big enough to deal with the whole of the air aspired by the machine, it would actually take considerably more than its intended share of the load.

One method of finding the volumes of the various cylinders is the "constant weight" method, which depends on the fact that (neglecting leakage) the weight of air in all the cylinders at the end of the suction stroke is the same, correction for leakage being made afterwards. Another method, which can be used graphically, is the "equivalent cylinder" method. Here the volumes of the ideal cylinders with no clearance are found, assuming the compression isothermal, and an adjustment is then made for the effect of clearance air and temperature rises.

When the cylinder sizes have been determined, the size, location and number of valves may be fixed, determining to a great extent the way in which the necessary clearance volume is made up.

Small deviations are often made from the theoretical figures for reasons of manufacture. Supposing that the calculated high-pressure cylinder diameter was 3⅜ in., for convenience of manufacture this dimension might possibly be made the more even figure of 3½ in., entailing, however, an increase of 7½ per cent. in the volume. Some builders, however, work to sixteenths of an inch in cylinder diameters.

Modern Multi-Stage Compressor Practice

Comparison with Steam Engines.—The care and consideration which must be given to the question of proportioning a compressor is probably of more importance then that required for, say, steam engine design, in addition to which the engineering practice for the successful construction of compressors must be of the highest order. In the case of a triple marine engine, the cylinder clearance volumes are of comparatively small importance, and the arrangement of the engine need not be altered to suit the clearances. Should the distribution of work be less even than as designed, it is only necessary to alter the cut-off in the different cylinders. The work done by the high-pressure cylinder can readily be reduced by cutting off earlier in the medium-pressure cylinder, but in an air compressor reduction of the high-pressure work entails the addition of clearance volume to the high-pressure cylinder, which addition it is usually almost impossible to effect.

Small errors in the calculation of steam engine design have sometimes been corrected by the introduction of packing pieces, or stepped keys in the valve gear, but with a compressor it is rarely possible to correct mistakes. The workmanship must be of the highest class, especially with such details as valves and high-pressure plungers. Piston rings and cylinder bores also call for particular attention.

A noteworthy difference between steam engine and compressor design is that, whereas with the great majority of steam engines the cylinders are double-acting, in high-pressure compressor work they are invariably single-acting in the generally accepted sense of the term. Another difference is the very frequent use of differential pistons, which are rarely met with in steam engines. These points give rise to a large number of possible arrangements of compressor cylinders, a few of which are shown diagrammatically in Figs. 19 to 29.

Cylinder Arrangements — Fig. 19 shows the most common arrangement of a three-stage compressor. On the down stroke air is drawn into the space marked low pressure through the suction valve, having previously passed through a silencer. On the up stroke this air is compressed, and delivered through the first stage intercooler to the annular space marked intermediate pressure, where, on the next down stroke, the second stage of compression is effected. The air is again cooled in an intercooler before passing to the high-pressure cylinder, where the final compression is carried out. Before the air is delivered to the storage bottles it is customary to pass it through an aftercooler (consisting usually of a submerged pipe), in order that the air in bottles shall not become unduly heated. This compressor arrangement is largely adopted on Diesel engines, as well as for independent plants on account of its comparative simplicity and compactness, but it has several disadvantages.

To examine or renew new-pressure or intermediate-pressure piston rings, it is generally necessary to lift the whole piston and connecting rod up through the cylinders before the gudgeon pin can be removed, which in some cases, such as in submarine engines, is an undesirable feature on account of the limited head-room usually available. It may also be noted that the low-pressure and intermediate-pressure work is all done in the same cylinder, as it were, so that more heat has to pass through the cylinder walls to the jacket than would be the case were an

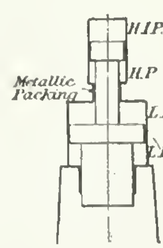

FIG. 29.

entirely separate cylinder devoted to each stage of compression. This, however, in practice is not of much moment.

Fig. 20 shows a small two-crank machine suitable for a motor-driven plant. With this type of machine the working parts are in constant thrust. A modification of this last arrangement is shown in Fig. 21, where both lines are driven by the same crank. This "V" compressor has been used on several marine Diesel engines, where the effect of the uneven turning moment resulting from this design is of but slight importance. It may be added that the angle of the "V" is usually somewhat less than that shown diagrammatically in the figure.

A curious adaptation of the type shown in Fig. 19 is given in Fig. 22. This arrangement, although expensive, has been used on some of the largest high-speed Diesel engines yet constructed, and is very satisfactory in operation. Instead of employing a single compressor, two entirely separate small machines are used, actuated from the ends of a rocking lever driven from the crank shaft by means of a single connecting rod.

A great advantage gained is a reduction in the size of cylinders necessary, which results in a marked improvement in the cooling and reliability. In addition, the turning moment of the combination is good, whilst the side thrust on the pistons resulting from the obliquity of the connecting rod in the usual design is, in this case, almost entirely absent. Another minor point to which attention may be directed is, that if a compressor valve breaks on, say, the starboard engine in a ship with this arrangement, only 25 per cent. of the main engine air supply is stopped, instead of half, as would be the case were each main engine fitted with a single compressor. As a result, it is quite likely that it would be found possible to carry on without running a big auxiliary compressor, which in many cases, being motor driven, entails the operation of a large generator set. Fig. 23 shows the arrangement occasionally adopted for Diesel engine work. Its obvious feature is its simplicity.

An arrangement which has been employed in one or two instances is shown diagrammatically in Fig. 24. Here the high-pressure stage is entirely separate from the other cylinders, and is driven by means of rocking levers. Accessibility is a feature of this design. To remove the intermediate-pressure piston it is only necessary to lift the intermediate-pressure cylinder cover and take off the nut securing the piston to the rod. By lifting the intermediate-pressure cylinder a little, it will now be a simple matter to withdraw the low-pressure piston. The high-pressure piston is easily withdrawn by putting the crank on top centre and uncoupling the link between the levers and piston. Note that the first stage of compression is effected on the under side of the low-pressure piston. This means that the heat from the intermediate pressure is well removed from the heat of the low pressure, so that the cooling is more efficient. The air in the space between the low-pressure and intermediate-pressure pistons is simply compressed on the up stroke, and re-expands on the down stroke—a relief valve being provided to guard against excessive pressurt due to piston ring leakage.

Fig. 25 gives another arrangement of compressor suitable for a Diesel engine, where the air displaced by the idle side of the low-pressure piston is passed to the idle side of the intermediate-pressure piston in a similar manner to the previous case.

In the arrangement shown in Fig. 26 each side of the large piston does a part of the first stage of compression, whilst the second stage is effected in a cylinder at the bottom, as shown. This necessitates the use of a gland subjected to a pressure of perhaps 300 lbs. per square inch as well as a high temperature, but this is of minor importance. The up and down loads are more nearly equal than is the case with the usual arrangement, and, in addition, the maximum crosshead load for a given capacity is reduced as a result of the decreased low-pressure piston diameter. It may be mentioned that this arrangement is adopted in one of the largest compressors yet built for Deisel engine work.

Figs. 27 and 28 show arrangements of four-stage compressors, suitable for torpedo air compressors. The former design necessitates glands, but permits of rather better cooling than the latter, which, however, has an advantage in that crossheads may be dispensed with if required.

A single-line four-stage arrangement is shown in Fig. 29, but this suffers somewhat from lack of accessibility, although the loads up and down can be equalized, as two stages of compression are carried out on each stroke. There are other arrangements to suit various conditions as to accessibility, compactness, balance, etc.

Cylinders and Piston Packing

The conditions under which compressor pistons run are different from those in a steam cylinder, where there is generally a certain amount of condensation and the water so formed acts as packing in an effective manner. In a compressor a little moisture from the atmosphere is present, but this is generally insufficient to permit of using, for instance, solid piston valves, as sometimes met with in steam practice. Special attention should be given to the question of piston packing, which, however perfect, is useless unless the cylinder bore is machined to within extremely fine limits, the required accuracy being greater the higher the pressure which has to be withstood. In the case of high-pressure cylinders opinion is divided as to the best means of producing the nearest approximation to the perfect bore. Some builders finish the bore by an elaborate system of reamers, and the accuracy and uniformity of the bore so produced leave little to be desired. Other manufacturers pin their faith to grinding methods, and in many cases the bore is lapped out to size. The packing used on high-pressure pistons is varied. For machines such as those used for torpedo charging, which only run intermittently, leather or some patent packing of a similar nature is used. Any slight unevenness in the bore or lack of alignment is taken up easily, and the leakage is very small. The question of temperature should not be overlooked, for if these are too high, burning of the packing will result, and in some cases, to reduce the possibility of this as far as possible, cylinder lubrication is effected by means of a comparatively copious supply of soap-water, oil being used but sparingly.

In compressors for pressures above 2,500 lbs. per square inch it is almost universal to find leather or similar high-pressure packing, and very frequently arrangements are made for introducing a certain amount of distilled water with the suction air. There are two ways of fixing the packing, one of which is to carry it on the piston, in the same way as piston rings, and the other is to use it in a similar method to that usually adopted with hydraulic machinery — the particular method adopted depending on the arrangement of the compressor.

For a Diesel engine compressor, or any machine which has to run at full load for long periods at a time, leather is not sufficiently durable, and recourse is made to metallic packing, consisting generally of piston rings. These rings are usually made of selected cast iron, and may be of the ordinary "Ramsbottom" or other types. Some builders adopt rather elaborate packing systems for high-pressure pistons which have special properties, such as being adjustable for axial wear and being self-aligning, whilst others use plain cast-iron rings with almost equally good results.

One point in this connection which may be mentioned is that "air packing" should never be adopted with high-pressure pistons, since the high-pressure air forces out the ring against the cylinder wall, and whilst giving a splendid result as far as air-tightness is concerned, increases the wear of the cylinder. Occasionally metallic packing is used in a type of gland, with, in some cases, satisfactory results. The packing may be of the manufactured ring form, or may be shredded white metal and graphite.

Regarding the other cylinders of the compressor, equal attention should be paid to the bores as with the high-pressure cylinder. The piston packing adopted consists usually of cast-iron rings, although some manufacturers fit leather or similar packing throughout the machine. For glands under air pressure, metallic packing is preferable, as the majority of the usual packings quickly deteriorate under the dry heat to which they are subjected.

Valves

The question of the design of valves for an air compressor is one which demands careful thought and attention, for no other part is so vital to the proper working of the machine. The type of valve used in all high-pressure compressors is the automatic valve, which depends for its action on a difference of pressure above and below it, and is not actuated by any external means. This appears in countless forms, but of few can it be said that they are entirely satisfactory.

Automatic valves are essentially of a more or less delicate construction, and the conditions under which they operate are usually severe. The delivery valves have to pass air at very high temperatures, and the heat, unlike that in a steam engine, is a dry heat; whilst in a high-speed machine running at, say, 450 r.p.m., the valves have to lift and seat themselves in a very short space of time.

For example, in a low-pressure cylinder in which compression is carried to 80 lb. per square inch gauge, at 450 r.p.m. the delivery valves have to open, pass the air, and completely seat themselves again in a period which is actually less than one-sixtieth part of a second. In order that this operation shall be successfully accomplished, either a powerful spring must be used to reseat the valve, or else the lift must be exceedingly small. The result of using a strong spring is that the pressure required to open the valve is excessive, and the hammering of the valve on its seat under the influence of the spring results in very rapid wear. The alternative, namely, the adoption of a small lift, means that the diameter of the seat must be large in order to obtain the requisite area through the valve for the flow of air. It may be stated that velocities in practice through the valve may be 130 ft. per second for low-pressure valves, and may be 250 ft. per second for high-pressure valves. If the diameter of the seat is increased over that sufficient with a larger lift, the leakage is increased, owing to the larger circumference of the contact circle; and, moreover, since a large valve is more liable to heat distortion than a small one, the possibilities of leakage are still greater.

Whatever the diameter of the valve, the weight should in every case be brought to the minimum. This reduces the inertia forces, and thereby the spring strength. Consequently the wear due to hammering and excess pressure required to open the valve is decreased. The type of valve usually employed for high-pressure work is the thimble valve, which can be used either for suction or delivery, two or more being used per cylinder to obtain the necessary area of flow. The valves proper are usually of nickel steel, and the seats of best quality bronze or gunmetal, although one Diesel engine builder used to fit valves in small compressors with seats of ebony or lignum vitæ. The actual seat should be as narrow as possible, in order that the unbalanced load may be reduced to a minimum.

For moderately high pressures small valves of the well-known plate type are frequently used. The plate is usually of special steel and the seat of bronze. It has been found in practice that this type of valve, at any rate in the larger sizes, is liable to fracture if the lift is too great, so that, in order to obtain sufficient area for the passage of the air and at the same time keep down the diameter, it is necessary to adopt multiple seats and to cut ports in the valve for the exit of a part of the air. Given suitable conditions, this type of valve when properly designed and made is superior to the thimble or poppet type, especially for the low-pressure stage, but the plates are somewhat unreliable when the temperature is excessive. One advantage over the other type is that carbonisation has very little effect on the working.

A type of valve to which one prominent Continental firm have pinned their faith is the "Gutermuth" valve, which consists essentially of a strip of steel wrapped round a spindle in a similar manner to a clock spring. This has been used with great success in all the stages of Diesel engine compressors up to quite large sizes.

In high-pressure compressor work the valves must be kept in thoroughly good condition, as otherwise a leakage may take place from any stage to a lower one, thus increasing the pressure and temperature attained in the latter. This would upset the balance, and in extreme cases cause a serious breakdown by adding, perhaps, 250 per cent. to the load on the connecting rod bolts. To guard against such contingencies it is of the utmost importance that ample relief valves be fitted to all stages, and however reliable a machine may appear to be, it is dangerous to run with the relief valves out of action.

It is not proposed to deal with mechanically moved valves, as their application to high-pressure compressor work is limited, usually to the low-pressure suction, with perhaps the addition of the intermediate-pressure suction. The great advantage of a mechanical suction valve for the low pressure is that one can ensure that the cylinder is filled with air at atmospheric pressure, instead of at a lower pressure due to the attenuation consequent upon a spring-loaded suction valve. If this mechanical valve is arranged in the piston itself, as is done in some designs, the cylinder clearance volume can be appreciably reduced. The delivery valves are invariably automatic. A valve gear which would adapt itself to the varying point of delivery with different pressures would obviously be somewhat complex. In high pressure work the necessity for this refinement is rather doubtful.

Regarding the disposition of valves, these are usually arranged in the cover of low-pressure cylinders in order to reduce clearance as far as possible, thereby seriously detracting from the cooling surface. Suction valves in the piston are not without disadvantages, since at the end of the suction stroke the inertia of the valve tends to seat it too soon and the cylinder is not fully filled with air. In some cases this arrangement necessitates the suction air being drawn through the crank case. It is argued that this tends to keep the running parts cool, but this is a doubtful advantage when it is remembered that the low-pressure compression starts with air which has been already heated, and is probably charged with oil vapor.

Cooling Arrangements

The importance of keeping low the temperature within a compressor has already been emphasized. High temperatures are detrimental to the satisfactory operation of the machine, and in addition result in an increase in the work required. Special attention should be given to cooling arrangements. The best time to effect the cooling is during the actual compression, as this tends to keep the compression low near the isothermal. There are two methods of cooling during compression, namely, jacketing the cylinder and injecting water into the compressor. Regarding the latter, it is necessary to use fresh or distilled water, as any deposit would have harmful results on the cylinder bores, valves, etc.

Jacketing.—This method, although efficacious to a certain point, is only used in a few isolated cases, and the majority of machines are fitted with water jackets, which act in exactly the same way as the jackets on internal combustion engines. In high-speed machines, however, jacketing is of comparatively little value on account of the rate at which heat is generated, and as a result the compression law approximates to the adiabatic. The conditions are sometimes aggravated by a bad arrangement of valves, or thick liner flanges just where the cooling is most wanted, and these points, coupled with bad jacket circulation caused by air locks resulting from faulty design, render the cooling on some machines practically valueless as far as the work done, etc., is concerned. On the other hand, in machines designed with large clearance volumes (the low-pressure cylinder, of course, excepted) the cooling can be considerably improved by using a submerged pipe to conduct the air between the cylinder proper and the valves. This means that there is an increase in the cooling surface, and, moreover, the cooling here can be effected under the best conditions as to conductivity of the walls, etc. Not only is the air cooled during compression, but it also loses heat during re-expansion, so that the incoming air meets with comparatively cool clearance air, which condition assists in keeping low the initial compression temperature, and thereby reducing the maximum cylinder temperature.

Intercoolers.—In practice, however, as is is impossible to deliver the air directly from one stage to the next in a cool condition, it becomes necessary to resort to intercooling. Between the stages the air is passed over a suitable cooling surface, which abstracts the remaining heat resulting from the compression in the lower stage, and the air enters the next stage cylinder in a cool state, the necessity for which has been previously explained. Intercoolers may consist of a simple coiled pipe, or may be of the multitubular type—similar to a surface condenser. The coiled pipe type takes up far more space per square foot of cooling surface than the multitubular variety, unless the construction of the machine permits of the coil being placed in the jacket round the cylinders, in which case a very compact arrangement is obtained at little cost.

FIFTY YEARS OF CONFEDERATION

UNLESS all signs fail, printers' ink, during the present and following weeks will be lavished with a free hand for the purpose of marking the completion of fifty years of Confederation of the individual provinces of this Dominion of Canada, the consummation of which on July 1, 1867, has contributed so materially to her development and progress in almost every direction during the elapsed period. That we have progressed and are still doing so, goes without saying, although when we look back—far or not so very far, is it surprising that we have reached our present status? When account is taken of the grit and dogged perseverance of the men from the Motherland who in the early days "blazed the trail," and with their immediate successors in many instances, made roads, built bridges, harnessed waterpowers, dug canals, pinned ribbons of steel to the soil and stretched it across a whole continent, initiated agricultural and mineral development, established manufacturing, built ships and sailed them on our lakes, rivers and ocean coasts, we in these later years must perforce admit that ours is a goodly heritage, not only to be cherished and retained intact, but to be developed in manner worthy of those from whom it has been received.

In the half century that has elapsed, much to be nationally proud of has been accomplished and, as might be expected, there has been and still is in evidence, much to the contrary. We are at war, and have been so for nigh three long years, and just what the new half century on which we are about to enter has in store is largely matter of conjecture. At war, yes, and in diverse ways we have been made to realize it. We are prosperous, yes, but there is an uncanniness about it that bids us take heed. We are progressing, but is the overwhelming tendency in the right direction? We are confident to the point of self-sufficiency, but is it all justifiable? While we have played a part, and a most worthy one up to the present, comparatively our vision, and consequently our activities, have been "cramped, cabined and confined." In a word, we have been poor "mixers." A new era in every phase of our national life has already been ushered in as a result of this world-war and, as a consequence, the trend of our past half century of progress is likely to evidence many offshoots if we would not only maintain our present position, but occupy those others that meantime are offering, and the possession of which will unfold a myriad others.

The omens are in every respect favorable to not only an unbroken continuance of the progress record of advancement of the past fifty years, but to its being stimulated in every sphere of our national life. Whether, in this war-time, we have done all we might or should have done, may be considered a moot point, everything considered. We have, however, not done badly, pharisaical even though the statement may seem; but much more is required and, needless to say, it is going to be forthcoming. We have a world-duty to perform, in the doing of which, our native or adopted country, as the case may be, will, as sure as night follows day, be a beneficiary. These are days when liberty —individual and national alike, are being strenuously assailed by tyranny of the foulest dye on the part of a sister nation, and to ensure that the part we have already played in the discomfiture of her tyranny may end in nothing short of her being completely squelched, if for no other reason, although there are others equally good, let the last fit man and the last, however hard-earned dollar, be spent.

In this issue features articles will be found covering specifically Canada's progress in a general sense, also that relating more particularly to the initiation and development of her machine tool and steel industries; supplemented by some detailed information covering her achievement in munitions manufacture, with conclusions drawn therefrom. In our July 5 issue the subjects of our railroad and general engineering progress will be given treatment relative to the elapsed period since Confederation.

MANNING CANADIAN BUILT MERCHANT SHIPS

RELATIVE to the shipbuilding and marine engineering activity now in evidence within our borders, and which is almost certain to extend well into the next decade, there is, in spite of the generally widespread appreciation of the fact that the meantime situation and outlook are so promising, apparently little, if any, thought being given to the matter of personnel wherewith to operate the large number of ships which will be produced on this continent in the coming months and years.

That it requires time—years indeed—to produce a marine engineer who can be entrusted with sole charge of a modern ship's machinery is evidenced by the requirements of the British Board of Trade in granting certificates, while the curricula prescribed is certainly such that few ordinary machine shop mechanics could at the moment approach with any degree of success. The necessity for additions to the supply of available marine engineers, however, is more than obvious to those most directly interested, and the certainty of an insistent demand in the near future for men capable of developing rapidly into high grade and efficient operators, is such that steps might very well be taken now to afford opportunity for the acquirement of the necessary knowledge.

No one will suggest for a moment that because a farm hand, who looked after agricultural machinery and had a mechanical bent, could run a lathe and do simple munitions operations, therefrom he became *ipso facto* a machinist. However, many machinists, tired of shop routine and repetitive operations, may well see in marine engineering an occupation for which they could quickly fit themselves so far as present general requirements are concerned, and which, when normal conditions return, would offer them possibilities for advancement and continuity of employment for two or three decades.

Present participation no doubt is accompanied by risks, but the latter have been taken by many others for the benefit of those yet to come, and the fact that present conditions have been brought about by the acceptance of these risks should act as a stimulant towards emulation.

INDUSTRIAL NOTABILITIES

LT.-COL. THE HON. FREDERIC NICHOLLS, president, Canadian General Electric Co., Toronto; president, Canada Foundry Co.; president, Canadian Allis-Chalmers, Ltd.; vice-president, Dominion Steel Corporation; president, Canadian Sunbeam Lamp Co.; president, Toronto & Hamilton Railway Co.; vice-president, Canadian Northern Quebec Railway Co.; vice-president, Dominion Coal Co.; vice-president, Dominion Iron & Steel Co.; vice-president, Electrical Development Co. of Ontario; vice-president, Sao Paulo Tramway, Light & Power Co.; vice-president, Toronto & Niagara Power Co.; vice-president, Toronto Power Co.; vice-president, Toronto Railway Co.; vice-president, Toronto & York Radial Railway Co.; director, British America Assurance Co.; director, Canadian Northern Railway Co.; director, Canadian Lake & Ocean Navigation Co.; director, Confederation Life Association; director, Imperial Rolling Stock Co.; director, Niagara, St. Catharines & Toronto Railway Co.; director, Toronto Electric Light Co.; director, Toronto Suburban Railway Co.; director, Toronto & Mimico Electric Railway; director, Western Assurance Co.; director, Great North Western Telegraph Co., was born in England, Nov. 23, 1856. He was educated at Stuttgart, Wurtemburg, Germany, and came to Canada, 1874.

The Senator has been prominently identified with the development of electricity, having organized the first company in Canada, the Toronto Incandescent Electric Light Co., which later adopted the underground system of electric distribution. He is a past-president, the National Electric Light Association of

LT.-COL. THE HON. FREDERIC NICHOLLS.

America, being the only Canadian who has held that position. This was in 1896. He is now an honorary member.

For seven years he was secretary of the Canadian Manufacturers' Association, founding its then official journal, and combining the dual role of editor and proprietor until 1893. He is Consul for Portugal; was president, the Toronto Press Club, 1890; president, the Athenaeum Club, 1893; is life member, Toronto Board of Trade; an honorary member, the Canadian Press Association; member of executive committee, the Canadian Manufacturers' Association; was made a J.P. and F.R.C.L. in 1911, and gazetted an Honorary Lieut.-Colonel, October, 1914. Appointment to the Senate came in January of this year.

During this war time the Senator occupies the following honorary positions: Member of the Executive Committee of the General Council of the Canadian Patriotic Fund; vice-president and chairman, Executive Committee, Toronto Branch Canadian Red Cross Society; president, Toronto Municipal Loan Association, a society formed to relieve distress.

He married Florence Graburn, daughter of Commander Graburn, in 1875 (deceased April, 1909).

His clubs are: Bankers' of America, N.Y.; York, Toronto, Toronto Hunt, Albany, Engineers', Ontario Jockey, Rosedale Golf, Toronto Golf, Scarboro Golf and Country, Hamilton Golf and Country, Royal Canadian Yacht, Mount Royal (Montreal); Rideau (Ottawa); Manitoba (Winnipeg); Mohawk (Schenectady, N.Y.). His recreations are hunting, fishing, motoring, yachting, golf. In politics he is Conservative, and in religious creed, Anglican.

His residences are 79 St. George St., Toronto, Ont., and "Parklands," Shanty Bay, Ont.

The General Market Condition and Tendency

THE abnormal conditions in the steel industry in the States continue to be reflected in Canada. As predicted last week, prices of a number of steel products have advanced, including iron and steel bars, plates, shapes, black, blue-annealed and galvanized sheets, Canada plates, wire and wire products. Consumers, anxious to obtain steel, are paying fancy prices and are thus assisting materially in the upward movement. The shortage of steel is becoming more acute, causing considerable inconvenience to consumers who are getting behind in their work, owing to their inability to get material on time. The Canadian mills are booked up for at least six months and their output is largely being absorbed for war purposes, thus private consumers have to rely on United States mills for a considerable proportion of their requirements. Extraordinary prices are being paid for ship plates and shapes, and some mills are refusing business, so heavy is the demand. Domestic foundry pig-irons are still off the market and no prices are being quoted. In the States pig-iron prices are still climbing and the end is not in sight. The situation in the market is unsatisfactory owing to the heavy demand and scarcity of pig-iron. Prices of coke are also advancing and production does not increase, although the demand is heavier. There is no change in the coal situation, but the outlook is improving. Prices of non-ferrous metals are unchanged from last week. The markets are dull with business practically at a standstill, as both producers and consumers are awaiting developments pending definite action on the part of the American Government. The scrap metal market is also dull and featureless. Consumers are staying out of the market hoping for lower prices which does not appear probable, owing to the scarcity of scrap and tendency to higher prices for all metals. The situation in the machine tool market is much the same as last week. Prices continue to advance and deliveries are getting more backward.

Montreal, Que., June 25, 1917.—While production of shells continues without any apparent signs of abatement, interest at the present time seems to be centered in the increasing activity in the ship building industry. In addition to the large number that are now actively engaged in the construction of various sizes of wood and steel vessels, indications point to a considerable increase to the plants that are already established. Wooden vessels will continue to be the chief feature of this reconstructed industry as long as the heavy requirements of the steel trade absorb the bulk of the supply of steel; even when the war ceases, it is improbable that immediate relief will come owing to the fact that plate facilities will still be inadequate to meet the demand that will continue for a long time after.

Pig Iron

Existing conditions would seem to indicate that the apex of the market is far from being attained as price advances are now so regular that a week's passage without a rise is more of a surprise that a sharp advance. The supplying of sufficient pig iron to meet the requirements of the steel industry is becoming the problem of the day, and the situation is expected to take on a further serious aspect in the early future. The average advance on pig in the Pittsburgh during the week has been 2½ dollars per ton, bessemer being now quoted at $58.95 and basic at $53.95 per ton. Relatively the same increase has taken place on other grades with the result that the composite price of pig iron is practically $50 per ton. With Canadian producers virtually out of the market, dealers here refuse to quote on this grade of pig iron.

Steel

Prices continue to climb to dizzy heights. The activity has shown slight decrease during the past week but the early prospects are for still heavier buying. The American government is still endeavoring to establish order out of chaos regarding the point of fixing prices that will be paid for various classes of material. This condition tends to maintain the market in a somewhat unsettled state but apparently has had no effect upon the sharp advances that are constantly taking place. The requirements of the United States Government are gradually attaining larger proportions, creating a situation where it is practically impossible for domestic consumers to secure material. Where the pressure is the greatest and where it will continue to be, is in the increasing requirements of the ship building industry; this activity being an essential factor in the many problems confronting the steel situation at the present time. In view of the prevailing conditions all quotations on steel materials are of a nominal character, owing to the daily uncertainty of political and industrial developments. The American situation is reflected in further upward bounds in price quotations: The Pittsburgh price on forging billets has been advanced $5 per ton, the current quotation being $125 per ton. Rolling billets quoted at $110 show an advance of $10 per ton. The urgency of ship construction has placed such a pressure on the plate mills that price advances are now a thing to be looked for overnight; during the week $20 per ton has been added to the American quotation on plates, the Pittsburgh base being now 9 cents per pound. Grooved and sheared steel skelp, which have been selling at 4 and 6 cents respectively, are now quoted at the nominal base of 8 cents per pound. Black and tin mill sheets, Pittsburgh, are now 9 cents, the week's advance corresponding to $20 per ton. The American market has again experienced a $10 per ton advance on wire products, the base on wire nails being now $4.00 per hundred. The local market has developed no new features and general conditions remain unchanged; much difficulty is still experienced in the securing of material and the domestic demand for general commercial purposes is fast becoming a negative quality. Dealers here anticipate a further advance on plates and other steel products in the very near future.

Metals

No important developments have taken place to disturb the general tone of the metal situation. The entire market seems to be awaiting the outcome of what the United States Government intend to do regarding the placing of contracts and the regulation of prices. Copper is quiet and slightly easier. Tin is uncertain owing to lack of English information. Spelter is not active but retains its strength. Lead has shown a slight falling off. Antimony is quiet with weak undertone. Aluminum is firm and unchanged.

Copper.—The position of this metal is well maintained, but uncertainty surrounds the general situation. The unsettled condition is the result of the delay on the part of the American Government regarding their requirements for their war program. Until this policy is definitely announced the market must necessarily be influenced by what might happen, and not by actual conditions. In the face of a quiet market New York quotations have shown a slight decline, ½c on lake and castings, and ¼c on electro; the current quotations being 31½c, 30½c and 32½c respectively. Local prices are firm and unchanged.

Tin.—While the market has fluctuated the situation at present is stronger than last week, due largely to the fact that information regarding conditions in England has not been forthcoming. The activities of submarines may have had something to do with this, but nothing definite has transpired to throw light on the actual cause. Conditions in the States are also tending to unsettle the market, as the attitude of the Government is of such a character as to retain the market in a state of nervousness. The situation this week shows an advance on the New York market of 1½c, the quotation being 63½c per pound. Dealers here are asking 63c, an advance over last week of ½c per lb.

Spelter.—Despite dullness the spelter market continues firm. The demand is very light for spot metal but the future positions are slightly more active. High production cost is the main factor in the steady strength of the market. A feature that may have some influence on future conditions is the efforts that are being put forth to find new uses for zinc, which in face of the high cost of other metals, may result in applying this particular metal to other useful purposes. Another decline of ⅛c has resulted on the New York market. The local situation remains quiet and quotations are unchanged at 12c per lb.

Lead.—Producers are taking a little more interest in the market and the situation this week has shown some relief over that of last week. In addition to this the output has materially increased and an easier undertone seem to be developing. A slight decline is noted in independent quotations on the New York market; the nominal outside price being now 12c per lb., a fall of ¼c per lb. Activity on the local market has developed further strength and dealers are asking 14¾c, this being an advance of ¾c per lb.

Antimony.—With the exception of futures, which are fairly active, the market remains quiet. Owing to the poor demand and the good supply the market has shown a weaker tendency with the New York market ½c easier than last week. Local dealers continue to quote 25c.

Machine Tools and Supplies

The demand for machine tools continues quiet more especially as regards the requirements of munition plants. Inquiry for this class of equipment is now almost confined to the replacing of worn out machinery with a few additional tools here and there to permit of balancing up on the various operations to meet increased output. General equipment seems to be again in fair demand, this apparently being to the increased activity in marine circles and the possibility of additional accessories being required to equip the many boats on the shipbuilding program. With new companies being formed and old ones developing the prospects for increased business for general equipment for machine shops seems more than likely. This latter activity is more pronounced in the United States where the building of boats of every description has become one of the essential industries of the present day. Both as regards machine tools and also supplies, the condition of the market in raw and semi-finished materials is an influencing factor on price quotations, the importance of which is a feature that requires much consideration on the part of the user of machine tools.

Scrap

On a comparatively quiet market prices have remained unchanged with the exception of a few grades of steel and iron scrap. A factor that appears to be influencing conditions generally is the feeling that some sort of readjustment is inevitable, either through the developments pending in the States or as the outcome of trade conditions. This uncertainty has resulted in unsettling the market and dealers are cautious regarding the purchase and stocking of material, as definite delivery to consumers hinges on the action of the railroads and the cars available for transportation. Local changes are confined to some of the heavier scraps, heavy melting steel, is now $20, wrought iron axles $23, and machine cast iron $25 per ton; advances on each being approximately $1 per ton.

Toronto, Ont., June 26.—The outstanding feature in industrial circles is the increasing shortage and high cost of all raw materials. The situation confronting the manufacturer is getting more serious and almost impossible to adjust, as the circumstances responsible for this condition are beyond his control. The delay in getting deliveries of raw materials hinders production, while the steady rise in costs makes it difficult to fix selling prices. Indications point to conditions becoming worse, as the war demand is increasing and all other considerations have to take second place. In spite of these handicaps the volume of trade continues to increase, and the country was never more prosperous in all its history. Canada has become an important factor in the commercial world, and in this respect has made big strides during the past two years. The number of factories, variety of product and the official trade returns are ample evidence of this. Foundations have been laid for greater activity in the future.

remarkable manner, hardly a day passes without some change in the price situation. A number of price changes predicted last week are now in effect, and all indications point to further advances in the near future. The local situation in the steel trade reflects conditions in the market in the United States. The advances this week include bars, plates, shapes, black and galvanized sheets, wire and wire products. The situation in the plate market is unprecedented, and extraordinary prices are being paid for ship material, some quotations being as high as 16c at Pittsburgh. Inquiries for thousands of tons of plates have again been turned down on account of the sold-up condition of the mills. The mills report that the output is practically normal, and they have all they can do for a year ahead without booking any additional tonnage. The new quotations for ¼-in. plate and larger is $11, heads $11.30, and tank plate $11.10. These prices, however, are largely nominal, as it is practically impossible to name a firm quotation. Iron bars are now quoted at 5.25c, steel bars 5.50c, and small shapes 5.75c base. Band steel is now 5.75c, chequered floor plate 3-16 in., 12.10c, and staybolt iron, 8.50c base. The new price on smooth steel wire, No. 0-9 gauge, is $6.50 per 100 lbs. base, while wire products have advanced in proportion, that is 25c per 100 lbs.

The position of the private consumer is becoming more difficult owing to the steady increase in war demand for steel. The American Government requirements of steel, which are the dominating factor in the trade in the U. S. at the present time, are affecting the situation in Canada to such an extent that material is very difficult to obtain in addition to the extraordinary high prices. Canadian consumers have now to rely upon American mills to a greater extent than in normal times, as domestic mills are filled up with war business. On this account the situation will get worse as the American Government requirements get heavier.

Prices of black and galvanized sheets have again advanced. Black No. 28 gauge is now $10, and No. 10 gauge $10..50. Premier No. 28 is $11.70 and 10¾ ozs. $12. Canada plates dull. $11, and bright, $12.50 per 100 lbs. These prices are higher, due to advances in the U. S. market. The American Government requirements continue to receive practically the entire attention of sheet manufacturers who are not making full deliveries even to old customers. Few sheet makers now feel in a position to make any sales because of the heavy calls for material by the Government.

Steel prices in the U. S. continue to climb with the average of leading products now about $115 a ton, as compared with $98 a ton two weeks ago. The demand for steel is acute, as many customers are months behind in their work owing to delays in getting deliveries of steel ordered long ago. The Government has not as yet definitely fixed prices on iron and steel products, and the situation is becoming more difficult to handle, as the cost of material is rapidly increasing. Consumers are so anxious to get steel that they are paying almost any price, and the market is more or less out of control. Iron and steel bars and shapes have advanced, as have also open-hearth billets.

Pig Iron

The market continues very strong with prices still climbing. Domestic foundry irons are still off the market, and consequently no prices are obtainable. The situation is acute owing to the steadily increasing demand, scarcity of iron and high prices. Prices are climbing so steadily that it is impossible to place much confidence in quotations more than a day old. Lake Superior charcoal iron has reached a maximum of $62 delivered Chicago. Pittsburgh dealers are quoting $60 Valley for basic iron, while low phosphorous is quoted at $82.50 Pittsburgh. Connellsville furnace coke is quoted at $12.50 ovens, with no improvement in production.

Scrap

The scrap market continues dull at unchanged quotations. Consumers appear to be waiting for lower prices, but in this they may be disappointed, as indications point to higher levels, particularly in the event of a buying movement developing. There is at the present time a decided scarcity of practically all old materials, which is naturally tending to keep prices up. Then, again, the increase in price of all new metals enhances the value of scrap.

Machine Tools

The sale during the week of some machine tools for making "gaines" has brightened up the munitions end of the business somewhat, but the demand for tools for ordinary purposes continues to be the chief feature in the trade. The renewed activity in the machine tool trade in the States is beginning to affect the Canadian market. Prices are still advancing, and deliveries are more backward, while it is highly probable that considerable trouble may be experienced in importing machine tools from the U. S. unless they are for munitions purposes. Government work is occupying the attention of the machine tool trade in the States to the exclusion of almost all other business. Canadian machine tool builders continue well employed.

Supplies

Prices of all machine shop and mill supplies continue very firm, with an upward tendency in some cases, particularly in iron, steel or brass goods. Castor oil is up 5c. being now quoted at 40c per lb. Lard oil has advanced 5c to $1.50 a gallon. Linseed oil is weaker, and prices have declined to $1.27 for raw and $1.30 for boiled oil. Turpentine is also lower, and is now 62½c per gallon.

Metals

The metal markets in New York have relapsed into a quiet condition, due to the uncertainty regarding the American Government requirements and probable prices. Under the circumstances producers and consumers are not inclined to do business preferring to wait developments. This situation is reflected locally and prices generally are unchanged, but holding steady. News of an interesting development in the metal situation comes to hand to the effect that some members of the zinc industry are engaged in trying to discover new uses for zinc. With the scarcity of some other metals and the comparative cheapness of zinc their efforts may very likely be successful. Lead may also come under examination, as the extremely high price of this metal has resulted in investigations being started to discover whether there are not some uses for which a cheaper substitute can be found.

Copper.—No new features have developed in the copper situation, the market being inactive, pending a decision regarding the price of American Government purchases. In the absence of actual business the nominal market quotations are unchanged. The strong feature of the market lies in the fact that the Allies copper contracts expire this month, and it is expected that a call will be made for a further supply. This, however, is somewhat offset by probable price concessions. Lake and electrolytic copper are quoted at 37c and castings at 36c per pound.

Tin.—With the market reacting in London, the local situation has become somewhat unsettled. Prices, however, are in the meantime unchanged, although a lower tendency is discernible. The tin market in New York continues quiet, with buyers uncertain as to what course to pursue pending a more definite information as to the intention of the Government in regard to prices. Local tin prices are unchanged and nominal at 66c per pound.

Spelter.—There is little change in the spelter situation. The market remains quiet, and is not even sustained by the hight cost of production. It is understood that negotiations are nearing completion at Washington by which the Government will purchase its next spelter requirements. Local price unchanged at 12c per pound.

Lead.—The American Government has agreed to purchase 8,000 tons of lead between now and August 1 at a price of 8c St. Louis. This decision has cleared the air somewhat, but the quantity is less than had been estimated. As a consequence the market is slightly easier, but quotations are unchanged. The "Trust" is quoting 11c, but independents are higher at 11.75c to 12c New York. Lead is quoted locally at 14¼c per lb.

Antimony.—The demand has fallen off during the last few days, though there is a fair amount of business going through for future delivery. Spot antimony is dull. Local quotations unchanged at 26c per pound.

Aluminum.—The situation is unchanged and demand is light. The market is weaker, but quotations are unchanged at 68c per pound.

Sydney, N.S., June 23.—Fusion of the Provincial Workmen's Association and the United Mine Works of Nova Scotia is now an accomplished fact under the new title of the Amalgamated Mine Workers of Nova Scotia. The new officers represent an equal number from the two amalgamating unions. With the absorption of the Provincial Workmen's Association into the new union there passes out of provincial affairs one of the oldest, if not the oldest, trade union in Canada. It has always been a purely provincial organization, as its name implies, and its record is in line with the best traditions of trades unionism. The passing of this old-established labor combination is a sign of the times, as it marks the passing of the conservative and extremely self-reliant and independent miner that was typical of the earlier days of the coal industry in Nova Scotia, and is a sign of the increasing influence and dominance of men of more advanced views. The fusion of the two unions is an indirect result of the war, and the ability of the more advanced labor advocates to make their influence felt because of the reluctance of the more conservative men to adopt a provocative attitude during the critical days of war times.

Weekly pays have been substituted for fortnightly pays at the Nova Scotian collieries since May 1. The result has been a lesser disturbance of working conditions on the days following the pay-day, but it is yet too soon to state what the cumulative effect will be. Some lessening of the disorganization after pay-days is also due to the great stringency of the enforcement of the prohibition laws that have supposedly been in operation in Nova Scotia for many years past. It is an undoubted fact that the Sydney district and the mining towns are "drier" than they have ever been before. The distinction is still comparative, however, and absolute prohibition has not yet been brought about.

Coal production is being steadily maintained. No great progress has been made in lifting the coal storage banks at Glace Bay. Bunker business continues very brisk.

The Dominion Iron & Steel Co. has undertaken to roll a limited tonnage of rails for the Canadian Government Railways. These will be the first rails that have been rolled for several years at its plant.

Pittsburgh, Pa., June 23.—The steel market is still more difficult to locate, as there is but little tonnage moving in the open market and each transaction is a law to itself. In a general way the market seems to be quotable about as follows, all Pittsburgh:

Tank plates	8.00—9.00
Blue annealed sheets ..	7.50—8.50
Black sheets	8.00—9.00
Steel bars	4.50—4.75
Refined iron bars......	4.75
Shapes	4.50—4.75
Wire nails	4.00

Generally speaking the deliveries would be in from three to six months. What makes the market so difficult to quote is that there is no regular forward delivery market. That has dropped out of sight, by common consent. The large buyers would not care to do business for the indefinite deliveries the large mills could make. Some do not see that they will need material after the country is fully in the war and others have a great deal of tonnage due them on which deliveries are very uncertain by reason of the precedence given to Government orders placed or to be placed. It is probable that in exceptional cases some mills are taking care of regular customers at prices less than those quoted as the market, but on the other hand they often refuse to quote at all, and if they quote for export it is generally at still higher prices.

Decreases in Requirements

At a time when the large mills are filled with business equal to six to ten months' production and are in line to receive much more from the Government in addition, the trend is towards a much smaller commercial consumption of steel. Large building operations are not being undertaken, except in rare instances. The fabricated steel jobs taken by members of the Bridge Builders' and Structural Society represented only 56½ per cent. of a month's capacity, rated at about 180,000 tons, and this month will show much smaller bookings. The railroads are practically wholly out of the market. The only commodity they might buy is rails, and they are given no opportunity. The rails they receive this year are costing them $28 for Bessemer and $30 for open-hearth, while the two $5 advances last year make the present nominal prices $38 and $40. The railroads can secure about $45 for old rails for remelting, say $50 for re-rollers, and up to $80 for relayers. Naturally the railroads would buy rails if they could.

In the automobile trade the slowing down is more noticeable each week, but it is not uniform among different makers. Some, like Ford, have heavier requirements than expected, but in general the automobile factories are specifying less against their contracts than formerly, and a much greater slowing down is to be extepected in the next two months.

U.S. Government Requirements

The U.S. Government has distributed orders for 81,000 tons of shell steel rounds for making 3-inch shrapnel and high explosive shell, at 3.75c., a price considerably lower than prices the Entente Allies have been paying for a twelve-month or thereabouts, some of the steel of which is still to be delivered. There is no further news as to the plans considered for the Government to buy 100,000 freight cars or more, together with some locomotives, to lease to the railroads for the duration of the war. A considerable tonnage of sheets has been distributed by the committee of three sheet manufacturers but prices, if already fixed, have not been announced. Nothing has been heard lately of the hangar program, which will involve a large tonnage of steel, as eventually the number will run well into the thousands.

Coke

Coke shipments from the Connellsville region have continued to prove insufficient for the blast furnaces tributary, on account of car shortage. Following representations made by blast furnace interests the Commission on Car Service at Washington promptly issued an order to the railroads under date of June 19, that the supplies to the region be increased 80 per cent. Next day the railway officials concerned held a meeting in Pittsburgh and expressed the opinion that they would be able to comply. The majority of coke producers are dubious, while the blast furnaces are hopeful. Spot furnace coke remains at about $12 per net ton at ovens, and on account of the uncertainties, operators will not make contracts for second half.

Pig Iron

Pig iron continues to rise, but hardly in as spectacular fashion as in May or early this month. Striking an average, the advance now seems to be at the rate of about $2 per ton per week. Minimum prices at valley furnaces (95 cents higher delivered Pittsburgh), are $50 for basic, $53 for malleable and foundry, and $55 for Bessemer, but slightly higher prices are being asked. It is beyond question that pig iron is scarce relative to the requirements of the steel works and foundries, and the common view among producers is that there will be further advances. Inasmuch, however, as nearly all the iron to be produced this year has been sold, and the chief market is for the first half of next year, there are other things to be considered, whether consumers will require as much iron nine months hence and whether production may not be greater, provided there is a better coke supply and furnaces now being built are completed. The by-product coke plants have had no serious difficulty and the Steel Corporation expects to have a part of its very large by-product plant at Clairton, near Pittsburgh, completed and in operation next September.

Industrial and Construction News

ENGINEERING

Windsor, Ont.—The Lake Erie Coal Co. propose to rebuild their plant which was recently damaged.

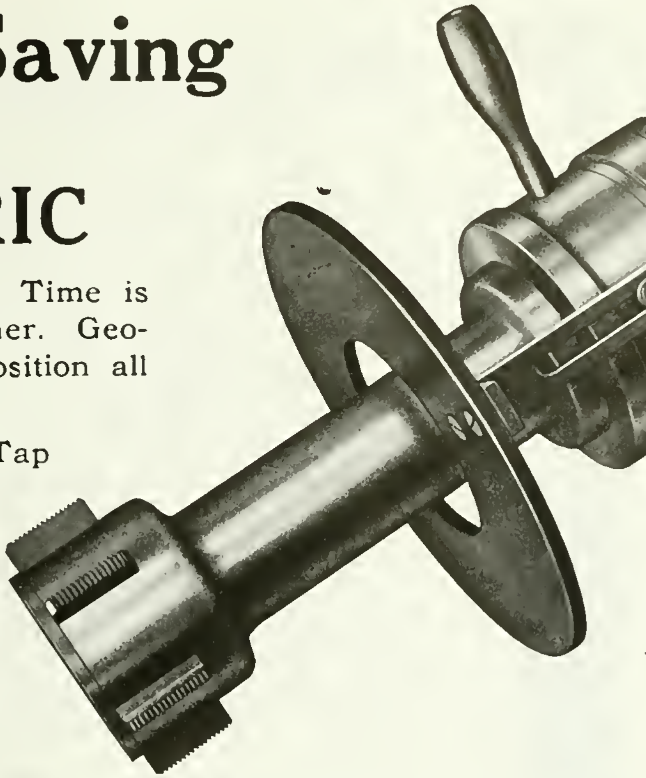
Vancouver, B.C.—It is understood that the aerodromes for the Lulu Island aviation field will be constructed by the contracting firm headed by Col. Lowe.

Toronto, Ont.—The Russell Motor Co. will build an addition to their plant on Dufferin street. The extension includes a machine shop, lunch and wash rooms, etc.

Hamilton, Ont.—The Provincial Government are building a power house at the Asylum here. Tenders are now being called for the reinforced concrete work.

Matheson, Ont.—Quite a large portion of the machinery for the new mill at the Croesus Mine, in Munro Township, has

Daylight Saving
with a
GEOMETRIC

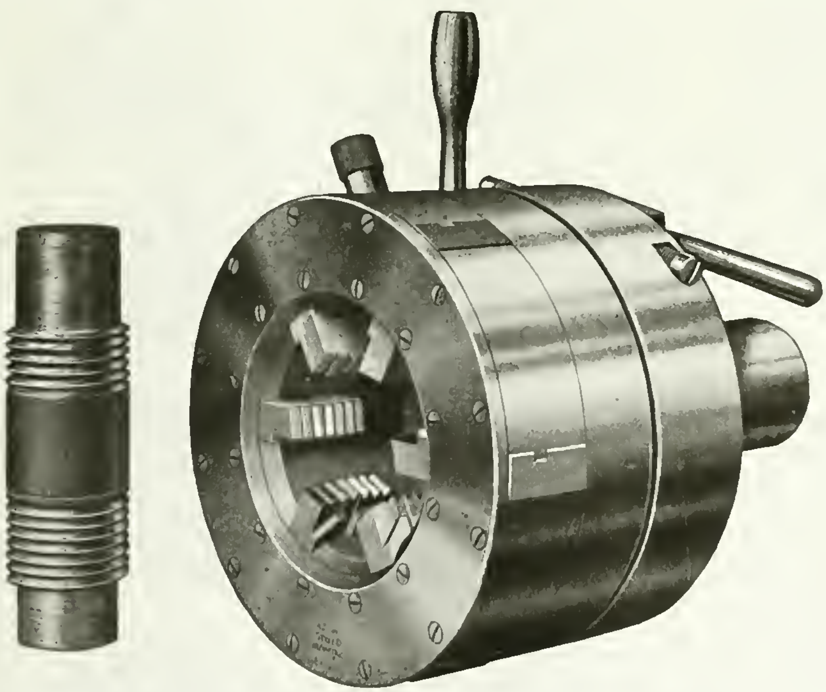


That is what it amounts to. Time is not the only thing saved, either. Geometrics are a saving proposition all around.

This Geometric Collapsing Tap is specially arranged for deep tapping in Projectile Caps.

All classes of thread tapping above ¾-inch diameter are taken care of by Geometric Collapsing Taps.

Twenty-five years of specializing in Screw Thread Cutting Tools has made the name GEOMETRIC stand for all that could be asked in Screw Thread Production.



When it is an outside thread, Geometric Die Heads cut every style from 1-16-inch size up to greatest required diameter.

A U.S. Navy Yard is using this 4½-inch size Style "D" Geometric Die Head. United States Navy Yards accept no second quality.

Do your Screw Machines and Turret Lathes swing Geometrics?

You have as much right to Geometric benefits as any other manufacturer.

The Geometric Tool Company, New Haven, Conn., U.S.A.

Canadian Agents:

Williams & Wilson, Ltd., Montreal. The A. R. Williams Machinery Co., Ltd., Toronto, Winnipeg, St. John, N.B.

now been installed, and it is expected the mill will be in operation before fall.

Brantford, Ont.—Fire on Sunday damaged part of Gould, Shapley & Muir's factory. The fire occurred in a frame building adjoining the main plant, and was prevented from spreading by the sprinkler system.

Fort William, Ont.—Crib work and foundation work on the new Eastern Terminal Elevator Co. new plant at Current river, Port Arthur, is now well under way, according to Superintendent R. D. Morgan, it is hoped that the elevator will be ready for operation by January 1st of next year. The tank foundations of the Saskatchewan Co-operative Elevator Co.'s buildings are being constructed.

Toronto, Ont.—The Polson Iron Works, Ltd., have had plans prepared for a new boiler shop, 250 ft. by 90 ft. wide. It will be of steel and concrete construction. The equipment will be the latest type, and will include an overhead electric travelling crane. The present boiler shop will be overhauled and re-fitted for an extension to the machine shop and engineering department. A new gantry crane, 65 ft. wide by 50 ft. high, of 10 tons capacity, is being erected on the east side of the dock. Other extensions include a lumber storage and auxiliary store house.

Port Coquitlam, B.C.—An agreement has been entered into between A. F. Bernstein and the Corporation of Port Coquitlam, B.C., to provide for the erection of an electrical smelting plant here consisting of four 25-tons per day units. The plant is also to be provided with a rolling mill, having an output of 75 tons per day. The company must produce 15,000 tons of pig iron per annum. The plant is designed to treat the magnetite ores of B.C. and construction will commence shortly. A by-law will be submitted to the electors shortly to authorize assistance by way of a bonus of $200,000, payable upon completion of the plant. Manso, Ramsay & Co., of Vancouver, B.C., are the consulting engineers to whom communications may be addressed.

MUNICIPAL

Peterboro, Ont.—The City Council have decided to purchase a combination chemical and hose wagon from the American La France Co., at $8,800.

Hamilton, Ont.—City Engineer E. R. Gray is preparing specifications for the additional steam and electrical equipment which will be installed at the pumping station. The cost is estimated at $127,000.

Oshawa, Ont.—The Town Council have given the first and second reading on a by-law to authorize an expenditure of $38,000 on a filtration plant. The John Ver Mehr Co., of Toronto, have already been awarded a provisional contract.

Hamilton, Ont.—The Board of Control have refused to acept any of the tenders submitted for a building to house the new civic weigh scales and its operator at a cost of $3,500, and instead will erect a chalet for the weigh scales, leaving the house for the operator in abeyance until next year.

Toronto, Ont.—A by-law will be submitted to the City Council to authorize an issue of bonds for $4,000,000 for harbor improvement work, and $720,000 for hydro-electric extensions. In the latter amount is included $350,000 for a substation and fixtures for the supplies of power to the steel plant on Ashbridges' Bay.

Chatham, Ont.—A movement has been inaugurated to instal a cold storage plant in connection with local Hydro station, making it possible for the committee to purchase butter, eggs, fish, and other perishable commodities in large quantities. The Public Utilities Commission is considering the matter, and it is possible that a recommendation will be made to carry out the proposal.

Hull, Que.—At the meeting of the City Council recently, the aldermen displayed much interest in a letter from Russell Blackburn, of the Ottawa and Hull Power and Manufacturing Co., asking for a fixed assessment on a plant it is proposed to construct at a cost of $400,000 on a dam adjoining the E. B. Eddy Co.'s mills. Nothing definite was done in regard to the application, but it was evident that the aldermen are anxious to have the plant erected.

GENERAL

London, Ont.—The London & Petrolea Barrel Co., will extend their plant here.

Toronto, Ont.—Willard's Chocolate, Ltd., will build an extension to their factory.

Hamilton, Ont.—The Canadian Shovel & Tool Co., will shortly commence the construction of an extension to their plant, to cost about $35,000.

Hamilton, Ont.—The Canadian Cotton Co., will build an addition to their factory at a cost of $60,000.

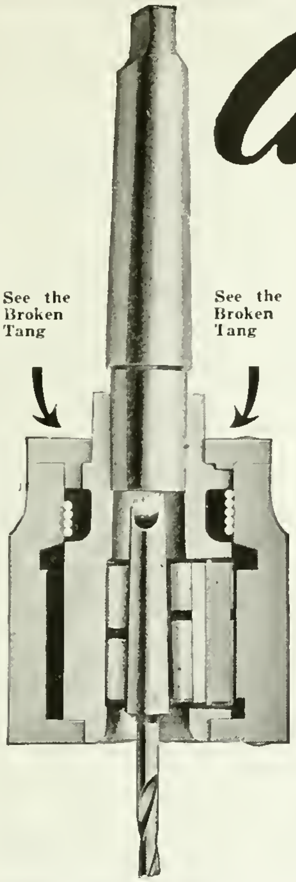
Hamilton, Ont.—Work on the new addition to the factory of the Proctor-Gamble Co., contemplated some months ago, will be begun immediately. A permit for the addition has been issued, the cost being estimated at $8,000.

Lanark, Ont.—The Clyde Woollen Mills, operated by the Boyd-Caldwell Co., here, were completely destroyed by fire last Thursday night. The loss is estimated at $150,000. W. C. Caldwell is the principal owner.

Sorel, Que.—Fire on June 19, practically wiped out the whole waterfront doing damage estimated at $250,000. The principal losses will be incurred by the Canada Steamship Lines, the Metropolitan Insurance Co., the Sorel Newspaper Co., the Bell Telephone Co., and the Dominion Government. Most of the damage was covered by insurance.

MARINE

Sault Ste. Marie, Ont.—A down-bound boat on June 21 reported passing through a field of ice 30 miles in length on Lake Superior.



Aikenhead's New Chuck

Don't Throw Away Broken Tang Drills

Perhaps you are about to discard some taper shank drills because the tangs are broken off—DON'T DO IT—they are worth their weight in gold. You can use them just as they are with a

Wahlstrom Automatic Chuck

One chuck holds drills from 1/16" to 1 1/4"

and you won't have to take time from your production to repair them.

Tool changes are made in two seconds—Just grasp the shell of the chuck with one hand and put in or remove the tool with the other—no collets—no lost time, for the spindle never stops. The jaws grip NOT BY THE TANG, BUT ON THE SIDE OF THE TAPER—there's no chance for slippage—a Wahlstrom won't even mar the shanks.

TORONTO - - CANADA

ON PAGE 150
You'll find a host of Opportunities.
TURN TO IT!

Vancouver, B.C.—The wooden vessels which the Western Canada Shipyards, Ltd., will build will be 2,800 gross tons, 280 feet long and 44 feet beam.

Draft Marked Up on Lakes. — The draft for the American lock at the Soo has been marked up two inches, and at the Canadian lock one inch. The draft for boats loading between Lake Superior and Ohio ports has been increased two inches, and boats running between Lake Michigan and Ohio ports can load four inches deeper.

Buoys in Operation Again.—It is announced that the submarine bell at Whitefish Point light station, Lake Superior, which was reported not ringing, was restored to commission June 17, and that North Point gas and bell buoy No. 1, Lake Huron, which was reported not burning, was re-lighted June 16.

New Westminster, B.C.—Preliminary to building four of the wooden steamers ordered by the Imperial Munitions Board, the New Westminster Construction & Engineering Co. is clearing the site for its shipyard on Poplar Island. The vessels will be 250 feet long by 44 feet beam, and will have a capacity of over a million and a half feet of lumber.

New Westminster, B.C.—A request for exemption from taxation for eight or ten years in consideration of the establishment of a wooden shipbuilding plant at Queensborough was laid before the City Council in committee recently by Messrs. Van Syckle and Macdonald, of Vancouver. The cost of the plant they propose to establish will be from $50.000 to $100.000.

Fort William, Ont.—The work of excavation has been started at the plant of the Great Lakes Dredging Co., on island number two, for the ways for the keel blocks of the first wooden ship to be built in Fort William. As soon as it is possible to get this done, the work of construction on the first of the wooden ships will be started.

Vancouver, B.C.—The little steamer Eva Maria, which piled up on a reef near Helmcken Island recently may be a total loss. Information received, states that the vessel is heeled over on the starboard side 140 degrees, practically capsized. The hull is badly twisted and the vessel is resting on the bilge and guard. All the seams have opened up and the boiler has shifted.

Vancouver, B.C.—Word has been received locally to the effect that T. A. Russell and R. E. Chisholm, of the Imperial Munitions Board of Toronto, will be here shortly with authority to let contracts for machinery for the vessels now being built for the board in British Columbia. It is understood that they are to make an inspection of the plants in British Columbia and if in their opinion the plants are able to take on the work they have authority to let contracts for a certain portion. The committee appointed to represent the British Columbia Metal Trades Association is keeping in close touch with R. P. Butchart and Capt. Troup in connection with the building of engines and auxiliary machinery of the ships to be built here.

CONTRACTS

Montreal, P.Q.—The Harbor Commission have awarded contract to the Cement-Gun Co., Toronto, for one G. L. N. type cement-gun.

Montreal, Que.—The Imperial Tobacco Co. have let a number of contracts in connection with the addition to the factory at St. Henri. The total cost will be about $100,000.

Sudbury, Ont.—The Town Council have awarded a contract for a steel standpipe to the Chicago Bridge & Iron Works, Bridgeburg, Ont., for $31,000.

Toronto, Ont.—McGregor & McIntyre have been awarded the structural steel contract for the new boiler shop for the Polson Iron Works.

INCORPORATIONS

Slater & Barton, Ltd., have been incorporated at Ottawa with a capital of $1,000,000. This concern is an amalgamation of the Allith Manufacturing Co. and the Acme Stamp & Tool Co., of Hamilton, Ont.

Electric Steel & Engineering, Ltd., has ben incorporated at Ottawa with a capital of $2,000,000 to manufacture steel and carry on the business of engineers and smelters etc., at Welland, Ont. The incorporators are J. S. Lovell. C. D. Magee and W. Bain all of Toronto.

Calgary Petrol Ltd., has been incorporated with a capital of $250,000 at Ottawa to manufacture and operate methods and apparatus for treating natural gas, petroleum etc., at Calgary, Alta. The incorporators are H. E. Foster, A. W. Dingman and C. W. Coale all of Calgary.

WOODWORKING

Vancouver, B.C.—The Dewar Shingle Co., contemplate building a shingle factory.

Owen Sound, Ont.—The Keenan Woodenware Co. will shortly commence building their factory here.

Port Arthur, Ont.—The Pigeon River Lumber Co., will start up their saw mill shortly, for the season.

Vancouver, B.C.—The Cameron Lumber Co. mills, near Selkirk Water, B.C.. together with the larger part of the machine shop, were destroyed by fire with a loss of $100,000.

TENDERS

Strathroy, Ont.—Town Council will call for tenders about July 1 for waterworks improvements, costing $10,000. Engineers, Kerry & Chase, Toronto.

Outremont, Que.—Tenders will be received up to July 18, for the construction of an incinerator. Specifications may be obtained from J. A. Duchastel, city engineer, City Hall.

Point Claire, Que.—Tenders will be received until June 27, for constructing filtration plant and installing pumps for the town council. Plans and specifications at office of the engineers, W. S. & R. S. Lea, 809 New Birks Bldg., Montreal.

Kingston, Ont.—Tenders will be received until July 16 for the reconstruction of part of the cribwork wharves at the entrance to the Dry Dock, at Kingston, Ont. Plans and forms of contract can be seen and specifications and forms of tender obtained at the Department of Public Works, Ottawa, the offices of the District Engineer, Equity Building, Toronto, Ont., and on application to the postmaster, at Kingston, Ont.

RAILWAYS—BRIDGES

Toronto, Ont.—Approval of the agreement between the city and the C.P.R. for the construction of a reinforced concrete structure to carry the railway tracks across the reservoir ravine to replace the present track bridge, was given by the Board of Control when submitted by Works Commissioner Harris a few days ago.

ELECTRICAL

St. Thomas, Ont.—The Town Council contemplate purchasing electrical equipment.

TRADE GOSSIP

Scarcity of Tungsten.—The demand for tungsten is heavier than the market can supply conveniently and prices are firm at current quotations, which range between $20 and $22 New York for high-grade material.

The Federal Engineering Co. have vacated their premises at Spadina avenue and have moved to more commodious and convenient quarters at 172 John street, Toronto. All friends attending the C. A. S. E. convention in July are requested to call and inspect the new offices.

P. & O. Amalgamate With Union S.S. Co.—The Peninsular & Oriental Steam Navigation Co. has amalgamated with the Union Steamship Co. of New Zealand, opening the Canadian-Australian line from Vancouver to Honolulu and Sydney, it was announced at Vancouver recently.

The Eastern Car Co. has opened an office in New York City, and Messrs. Gordon M. Graham and Joseph Eaton, of New Glasgow, N.S., will look after the interests of the firm there. Their duties will be largely in connection with the export of material used in the manufacture of cars for foreign orders.

Australian Scheme to Develop Industries.—The Melbourne Age says that the Federal Ministers are considering a scheme for providing for the expenditure, over a term of years, of at least £10,000,000, on the establishment of certain factories under joint private and Government supervision. The scheme includes the creation of a national industrial department in close contact witn the Commonwealth banks.

Exports Mostly to Britain.—The Minister of Finance stated recently in the House of Commons, Ottawa, that the total merchandise exported to foreign countries from August 1, 1914, to March

31, 1917, amounted to $2,287,557,612. Of this amount $1,380,253,928 went to Great Britain and $634,741,601 to the United States. Merchandise to the value of $2,675 was loaded for Germany prior to the outbreak of war. The Government, however, has no record of shipments to Hamburg, Germany.

The Storey Pump & Equipment Co., Toronto, have supplied two 3 in. four stage Morris turbine pumps to the Ontario Hydro-Electric Commission for the Chippewa Creek development.

Dominion Bridge May Build Ships.—Dominion Bridge officials are reticent as to future plans of the company in regard to the shipbuilding business, but there is a rumor that the company is about to enter that field. General Manager Duggan has had several visits to Halifax and Sydney of late, where he has conferred with the Beardmore and English interests. It is reported from the East that tentative arrangements have been made with one of the big steel companies for the erection of mills for the rolling of steel plates.

Government Ready to Operate Mines.—Replying to a question in the House of Commons, Ottawa, on June 21, about the Western coal mine situation, Hon. T. W. Crothers, Minister of Labor, stated that the mines would be in operation within a few days under the guidance of the Government, unless the operators and miners got together. The only point in dispute was the penalty clause, which the operators insisted upon putting into the contract. Both sides were willing to accept the scale of wages proposed by the Government special commissioner, R. F. Green, M.P.

Steel Price Inquiry.—The United States Government inquiry into steel making costs, in the opinion of manufacturers may develop facts likely to reduce the bickering reported from Washington. It will show, for one thing, that one company's expense in making plates, steel bars, structural forms, etc., is by no means the same as the expenses of another concern. It is pointed out that while the Steel Corporation might show good profits on ship plates, say, at a certain price, a competing concern, with a smaller output, would not make any money at all at the same figure. In the steel trade the uncertainty over prices, for Government work is reported to be making the price situation in commercial lines more confused than it has been before in this exceptional year.

Toronto Hydro Has Good Year.—The Toronto Hydro-Electric System during the year ending 31st December, 1916, has made a surplus of $18,397. This sum would have been $200,000 had the rates not been reduced, according to the sixth annual report, just issued. The gross income for the year totalled $1,706,177. The cost for electric power and expenses, etc., amounted to $1,072,134, while $615,646 went in interest, sinking fund and depreciation, leaving a balance of $18,396. The report shows that last year between 20,000 h.p. and 30,000 h.p. has been supplied to munition factories. This amount will probably be greatly increased this year. The report states further that by strict economy the expenses for operation have again been put below the figures for the preceding year.

Oil Tanker Reginolite Launched.—On June 21, at the yards of the Collingwood shipbuilding Co., the fourth oil tank steamer which the company is building for the Imperial Oil Co., was successfully launched. There was no ceremony and comparatively few spectators. The new boat, which will bear the name Reginolite, is intended for ocean service. It is 250 feet over all, 43 feet 9 inches beam, and 25 feet deep to the upper deck. The motive power consists of a set of triple expansion engines, supplied with steam by two Scotch boilers, 13-6 by 11 feet, working at 180 pounds pressure. The construction of the steamer is in accord with Lloyds registry for ocean-going boats. The fifth boat of the Imperial Oil Company's order will be launched shortly, and will be named Talaroite.

Commercial Steel Outlook.—Comment heard in the steel trade in the United States shows an expectation of a decreased commercial consumption when the Government buying campaign gets under way. The shrinkage ,in the opinion of steel makers, should be gradual, responsive to the rate of inflow of Government orders. There is no way of estimating the extent of steel mill capacity to be devoted to Government business this year. Buying will not mean that the orders placed are to be filled at once, although in certain lines, as ship plates and forms for ships, all haste will undoubtedly be made to fill contracts. The Government presumably will figure on requirements many months ahead and, with the pressure of manufacturing spread over a long period, no serious derangement to existing mill schedules is looked for.

Commission Will Fix Steel Prices.—At the request of Secretary Daniels and Chairman Denman of the United States Shipping Board the Federal Trade Commission will undertake an investigation looking to the fixing of an equitable price for steel. The Commission will be aided by James A. Farrell, President of the U.S. Steel Corporation and the Munitions Board of the Council of National Defence. Not only will a price be fixed for steel, but also for all materials, including coal and coke, entering into the manufacture of steel. The prices fixed by the Commission will not be arbitrarily imposed. The manufacturers will be invited to co-operate with the Government to the extent of furnishing the material for food ships and naval construction at a price the Commission considers just. Failing in its efforts at voluntary co-operation, the Commission will make a report to Congress similar to its report on coal and transportation two days ago, in which it will recommend the pooling of the steel interests of the country to be operated by a Government agency on Government account.

PERSONAL

Hon. W. J. Hanna, of the Imperial Oil Co., Toronto, has been appointed food controller by the Dominion Government.

H. R. Storey, purser of the steamer Hamonic of the Northern Navigation Co., has resigned and accepted the management of a line of steamers on Georgian Bay.

A. W. Heath, of Hamilton, Ont., executive treasurer of the C. A. S. E., after undergoing a serious operation, has left the hospital, and is now well on the way to recovery.

Frederick S. Viney, formerly with Westinghouse, Church, Kerr & Co., New York City, has assumed charge of the electrical department of F. R. J. MacPherson Co., Peterboro, Ont.

W. H. Armstrong, of Vancouver, B.C., has been appointed by the Dominion Government Director of Coal Mining Operations in south-eastern British Columbia and south-western Alberta.

Charles Newton Candee, president of the Gutta Percha and Rubber Co., has been appointed a director of the Canadian Bank of Commerce. Mr. Candee has been connected with the rubber industry for several years.

A. P. Broadhead, Superintendent of the Southern Canada Power Co., at St. Johns, Que., is leaving, on or about July 1 to asume a similar position, though with wider powers and more territory, with the same company at Granby, Que.

Frank H. Crockard, vice-president and general manager of the Tennessee Coal, Iron & Ry. Co., Birmingham, Ala., has been appointed president of the Nova Scotia Steel & Coal Co., to succeed Col. Thomas Cantley, Chairman of the Board of Directors.

Col. Thomas Cantley has resigned from the presidency of the Nova Scotia Steel & Coal Co., to assume the position of chairman of the Board of Directors. Col. Cantley has been with the company 32 years, of which 16 were spent as general manager and two as president.

J. P. Henry, who held an important position with the National Cash Register Co., of Dayton, Ohio, has taken over his duties as factory manager of the new plant of the Canada Cycle and Motor Co. at Weston, Ont. Mr. Henry is a native of Scotland.

Samuel King, of London, Ont., has been appointed managing-director of the National Steel Car Co., of Hamilton, Ont., in place of Basil Magor, who recently resigned. T. O. Scott, formerly secretary of the Canadian Tungsten Lamp Co., of Hamilton, has been appointed secretary-treasurer.

T. S. Dickson, of William Beardmore & Co., shipbuilders, Glasgow, is in this country for the purpose of selecting a site for an extensive steel shipbuilding and dry dock plant. It has been definitely settled that a plant will be built in Canada. In company with A. D. Swan, consulting engineer, Montreal, Mr. Dickson has inspected sites at Montreal, Que.; Halifax, N.S., and St. John, N.B.

George A. Morrow, president of the Imperial Life Association, Toronto, has been appointed Director of Aviation in Canada by the Dominion Government. Mr. Morrow suceeds Frank W. Baillie, who as president of the Canadian Aero planes Ltd., Toronto will be enabled to devote more time to this concern. Both are serving without remuneration.

President Mark Workman of the Dominion Steel Corporation has left Montreal for the company's properties in the East. He will be away about two weeks. During that time he will first inspect the new blast furnaces and by-product ovens being installed at Sydney. From Sydney he will cross to Wabana, Nfld., where work has been started on the improvements planned in connection with an increased output of iron ore.

Sir Alexander R. Binnie, the well-known engineer, died at his home in Devonshire, England, in May. He carried out many important public works and was president of the Institute of Civil Engineers in 1905-6. Sir Alexander investigated the Ottawa water supply a few years ago and recommended a scheme which was afterwards abandoned on account of the heavy cost.

James R. Phillips, of the firm of J. G. Greey, mill machinery engineers, Toronto, died in the General Hospital last Friday, as the result of burning injuries sustained at the works. The late Mr. Phillips was born in the Township of Vaughan 63 years ago. On coming to Toronto he joined the John Abell Co., and later became superintendent for the Pease Foundry Co., a position which he held for 24 years. Fifteen months ago he became associated with J. G. Greey Co.

Capt. T. E. Ryder, who has recently been promoted for distinguished conduct, is manager of the Canadian Fairbanks-Morse Co., St. John, N.B., on leave of absence for active service. Capt. Ryder has also been awarded the Military Cross, and on more than one occasion mentioned in despatches. He was, previous to the war, an officer in the St. John Battery. When war broke out he immediately enlisted for active service, and was attached to the Ammunition Column, Heavy Battery.

CATALOGUES

Rubber Belting.—Booklet issued by the Goodyear Tire & Rubber Co., Toronto, containing a standard rubber belting price list and a list of firms using this concern's goods.

Air Compressors.—The CanadianIngersoll-Rand Co., Montreal, have issued a new bulletin describing their class FL-1 steam-driven, single stage, straight line, air compressors. The construction and principal features of this machine are described fully, accompanied by detail illustrations and general views.

Air Compressors.—Bulletin K-302, 16 pages 6 x 9 in. illustrating a line of steam driven, straight line, single stage air compressors manufactured by the Canadian Ingersoll-Rand Co., Ltd., of Montreal. The type of machine described is designed to cover the field of those requiring compact, self-contained units of small and medium size for service in shop, foundry, mill or electrical plant, etc. Automatic splash lubrication, dust-proof construction, "Circo" silent leaf valves and quick convertibility to melt drive are among the leading features of the design dwelt upon in this publication.

Pipe Threading Machinery, made by the Landis Machine Co., Waynesboro, Pa., is the title of catalogue No. 23, just off the press. This catalogue illustrates and describes in detail the Landis stationary pipe die head, pipe threading and cutting machines, pipe and nipple threading die heads, pipe and nipple threading machines, and the Landis chaser grinders. The catalogue sets forth the distinctive features of the Landis product, and also contains specifications covering the various types of machinery described. A detailed list of parts is also included.

The Stroh Steel Hardening Process Co., Pittsburgh, Pa., have issued an attractive-looking catalogue describing the Stroh process for making steel castings. The catalogue states what the Stroh process is and the theory of it. A number of steel castings, made by this process, are illustrated, showing the suitability of this method, particularly for making castings for certain purposes, such as gear wheels, pinions and car wheels, etc., where the service is exceptionally severe. The including pages trace the history of steel castings from pre-historic times until the present day featuring the Stroh process.

BOOK REVIEW

"The Driving of Machine Tools," by Thos. R. Shaw, is the title of an engineering handbook recently published by Scott, Greenwood and Son, of London E.C. Price $1 net. In the compilation of this work it has not been the aim of the author to go extensively into the fundamental details of design, involving the use of intricate formulae and calculations, but rather to deal with the subject of machine tool drives in a general way, illustrating the various methods now in use and their application to the different tools, with a view of instructing, and possibly advising, mechanics and designers in the adaptation of certain principles, in order to attain the highest efficiency in the transmission of power to machine tools. The book is of convenient size for ready reference, being 5 by 7 inches, 220 pages, with 139 illustrations and 37 tables. The text is divided into eight chapters and an appendix, covering durability and accessibility; cone pulleys and gearing; application of care pulleys; the all gear drive; application of motor drive; planing machine drive; drives for various machines, and miscellanies. The concluding chapter of the book describes a number of auxiliary details incidental to general machine operation, such as the use of ball bearings, spiral gearing, belt drives, rules, tables, etc. This work should commend itself to any connected with the design of machine tools, or the application of drives for the operation of the same.

FOR SALE

FOR SALE — 1 HOLDEN-MORGAN BASE milling machine, 3-inch shell. Manitoba Bridge & Iron Works, Winnipeg.

1 24" CONRADSON TURRET LATHE. APPLY McGregor, McIntyre, Limited, Toronto, Ont. c3m

FOR SALE—ONE LEWIS TYPE ENGINE built by Waterous Engine Works, 240 H.P., flywheel 73" x 18", automatic governor, a bargain. One steam pump, 4½" x 2¾" x 4". Write Box 217, Moncton, N.B. c24m

RADIAL DRILL, 4' CINCINNATI BICKFORD with single pulley drive and speed box, for sale or exchange for 6" Radial Drill; also Mitts & Merrill Keyseater, 12" stroke to cut 2" wide keyways. Boving Hydraulic & Engineering Co., Ltd., Lindsay, Ont. c26m

FOR SALE—TWO 16 x 6 REED PRENTICE Automatic Lathes. One Bertram Gap Lathe, 48 x 10. Four No. 10 Heavy Duty Baker Drills. One No. 2D Colburne Drill. One Heavy Duty Reliance Machine Co. Turret Lathe for inside boring of 6" shells. Canadian Blower & Forge Co., Kitchener, Ont. c24m

WE HAVE ON HAND AT OUR WELLAND Works, for disposal, the following new machinery:—One (1) 18" x 15 ft. Accumulator; one (1) Aldrich Triplex Hydraulic Pump, 180 gals. capacity; two (2) 350-ton B. and B. Presses. All offers will be carefully considered. Canadian Car & Foundry Co., Ltd., Transportation Building, Montreal.

1—ROBB HORIZONTAL STEAM ENGINE, 10 x 12, 35 h.p. Just overhauled by makers. Price $300.00. 1—Heavy Duty Rockford Drill. Suitable for shells or heavy work. Weight of drill 3,600 lbs. Good as new. Write for specification. 1—Jones & Lamson 2 x 24 Turret Lathe, 2¼" hole in spindle, 16" swing, cone drive, collet chucks for bars up to 2" diameter. Or lathe can be fitted with standard universal chuck. Flat turret 16" diameter. Good condition. Price $400.00. 1—Warner & Swasey Turret Lathe. Round turret, diameter 8", hand cross feed for turret. Swing 14". Fairly good condition. Price $200.00. 1—Bertram 2-spindle Thread Miller. Made by makers for threading 18-pdr. shells. Now used for threading sockets. Good condition. Steel Furnishing Co., Ltd., New Glasgow, Nova Scotia. c2m

BUSINESS CHANCES

SHELL PLANT FOR SALE — COMPLETE plant—installed since 1914, for the machining and assembling of 4.5 inch H.E. shells, situated at Dartmouth, Nova Scotia, on line of Intercolonial Railway, with siding running into the works. Will sell the equipment outright, with privilege of renting the building in event of the purchaser engaging in the same business. Starr Manufacturing Co., Limited, Dartmouth, Nova Scotia, Canada. c26m

FOR SALE—A MEDIUM-SIZED TWO-STOREY brick factory situated in the best small city in Ontario. Buildings in good condition, suitable for either metal or wood-working; shipping facilities unexcelled. Two trunk lines; direct connections east, west, north and south. Educational advantages the very best. Plant will be sold at a bargain and on easy terms of payment, if desired. Apply Box 294, Canadian Machinery. c2m

WANTED

WANTED — THREE GOOD SECOND-HAND air hoists 3" diameter by 4' lift. McKinnon Dash Company, St. Catharines, Ont. c26m

300-TON PRESS SUITABLE FOR NOSING 4.5 Howitzer Shells, complete with triple pump, accumulator, and fittings. McGregor & McIntyre, Limited, 1139 Shaw St., Toronto, Ont. c26m

WANTED—THREAD MILLER FOR NOSE OF 4.5 mark VII. shell. Must be in good order and price reasonable. J. C. Wilson & Co., Belleville, Ont. c26m

4—New 14" Pierce Turret Lathes.
2—New 1 x 8 Pierce Hand Screw Machines.
2—2" Cleveland Automatic Screw Machines, jigger feed.

MILLING MACHINES AND PLANERS.

5—No. 1½ Knight Milling and Drilling Machines.
2—No. 13 Pratt & Whitney Lincoln Type Milling Machines.
1—No. 1 Cincinnati Plain Milling Machine.
3—Fox Hand Milling Machines.
1—Garvin Hand Miller.
1—27 x 27 x 7' Cincinnati Planer.
1—22 x 22 x 5' New Haven Planer.
1—20 x 20 x 3' New Haven Planer.

DRILL PRESSES.

1—24" Baker Heavy Duty High Speed Drill.
1—3-spindle 8" overhang Henry & Wright High Speed Drill.
3—12" Leland & Gifford High Speed Bench Drills.
5—20" Buffalo Plain Drill Presses.
4—6-spindle Fox High Speed Drill Presses.
2—4-spindle Fox High Speed Drill Presses.
1—3' Mueller Plain Radial Drill.
1—6' Mueller Plain Radial Drill.

SHAPERS AND SLOTTERS.

1—24" New Barker Crank Shaper.
1—24" Lodge & Davis Geared Shaper.
1—18" Hendey Geared Shaper.
1—16" Hendey Geared Shaper.
1—16" Garvin Shaper.
1—16" Ohio Crank Shaper.
1—16" Smith & Mills B.G. Crank Shaper.
2—16" New Springfield B.G. Crank Shapers.
1 24" Niles Geared Type Slotter.

PRESSES AND HAMMERS.

1—Waterbury Farrell Straight-sided Geared Press with double cam knock-out.
5—No. 2-W Bliss Wiring Presses.
1—800-lb. B. & S. Roll Board Hammer.
1—800-lb. Pratt & Whitney Roll Board Hammer.
1—50-lb. Scranton Belt Hammer.
1—24-lb. Bradley Helve Hammer.

AIR COMPRESSORS.

1—8 x 6 Westinghouse Steam Air Compressor.
1—16 x 18 x 12 Union Steam Pump Co. Steam Driven Air Compressor.
1—10 x 10 Ingersoll Sargent Belt-driven Air Compressor.
1—10 x 10 Clayton Belt-driven Air Compressor.
1—9 x 8 Ingersoll-Rand Belt-driven Air Compressor.
1—8 x 8 Fairbanks-Morse Electrical-driven Air Compressor.
1—8 x 8 Gardner Single Belt-driven Air Compressor.
1—8 x 8 Union Steam Pump Co.'s Belt Air Compressor.
1—7½ x 6 Chicago Pneumatic Tool Co. Belt-driven Air Compressor.
1—6 x 6 Chicago Pneumatic Tool Co. Belt-driven Air Compressor.

We also carry a large stock of Steam Engines, Steam Pumps, and Electrical Equipment of all kinds.

We are in the market to purchase machine tools, both large and small.

24" x 16' Pond Machine Works, compound rest lathe; very good.

24" x 24' Pond lathe, arranged for shaft turning with taper att., turning rest, full equipment for plain or screw cutting work; very good condition.

No. 1 Landis full universal grinder capacity 10" x 20" for external, internal and face grinding; machine has belt feed, overhead counter shaft; very good condition.

36 x 16 Gould & Eberhardt spur gear cutter, pinion type.

12" Bement Miles slotter, 11" stroke, 32" table, all power feeds, cone drive for 4" belt, all in excellent condition; used very little.

75 lb. and 15-lb. Bradley upright helve hammers; good.

Grant Lees gear hobber capacity about 18 x 1 in. spurs, spirals or bevels; good condition.

Peerless high speed cut off saws; 6" capacity.

2—[illegible]B Bliss toggle drawing press, capacity to draw and lift out 8".

1[illegible]2 Toledo single back-geared toggle drawing press, practically new capacity to draw and lift out 1"

36" Cresent wood band saw; almost new.

2 hand operated 5-ton traveling cranes, 18' span, almost new.

Greenfield Universal tool and cutter grinder complete and in good condition.

No. 2 Stiles punch press, 24" fly wheel, 12" throat, 1½" stroke; very good.

National Acme 1" x 6" automatic steel threading machine almost new.

FOR SALE

BORING MACHINE—VERTICAL.

1—30" Colburn, 1 turret head.
1—New 30" Gisholt, one turret head, Sept. delivery.
1—34"-42" New Colburn, one turret head, Aug. delivery.
1—34" Rogers, one turret head, Sept. delivery.
1—36" N-B-P, one plain and one swivel head.
2—36" B. & S., one turret head.
1—53" N-B-P, two swivel heads.
1—72" Niles, two swivel heads.

BORING MACHINES—HORIZONTAL.

1 Lucas, 2¼" bar.
1—New No. 1 Cleveland, 2½" bar.
1—Hoefer Horizontal Driller and Borer with 1 11-16" spindle, vertical adjustment 40", horizontal adjustment 46", size of table 33" x 48".
1—No. 4 Beaman & Smith Floor Type, 5" bar, also 10" boring bar and 2 facing heads; also boring heads, with floor plate 8' x 11'.
1—Special Floor and Cylinder Borer, with 12" bar, 158" swing, vertical travel on column, but no cross travel, size floor plate 20' x 14'.

BULLDOZERS.

1—New No. 4 Garrison, same specification as No. 4 Williams & White.
1—No. 7 Ajax, 20" stroke.
1—No. 7 High-speed Ajax, 16" stroke.

COMPRESSORS—AIR.

1—8" x 8" Curtis, belt-driven.
1—10" x 10" x 10" Single Cylinder Smith-Vaile, steam driven.
1—10" x 12" Chicago Pneumatic, belt driven.
1—12" x 12" American, belt driven.
1—16" x 12" Chicago Pneumatic, Duplex, belt driven.
1—10"-16½" x 13" Peerless, cross compound, steam driven.
1—22"-13" x 16" Ingersoll-Rand, motor driven.

CUTTING-OFF MACHINES.

2—No. 0 Brown & Sharpe.
1—2" capacity Warner & Swasey.
2—3" Curtis & Curtis.
3—4" Curtis & Curtis.

CRANES—ELECTRIC.

1—5-ton P. & W., 4-motor, 10' span, 25' lift, 220 v., D.C., with one ton auxiliary hoist.
1—8-ton Phoenix, 38' 10" span, 220 v., D.C.

DRILLING MACHINES—RADIAL.

1—New 3' Mueller plain, speed box drive.
1—36" Bickford, plain, speed box drive.
1—New 3½' Mueller, cone drive, July delivery.
1—New 3½' Carlton, cone pulley drive.
1—New 3½' Western, July delivery.
2—4' Mueller plain, speed box drive.
1—5' Bickford, plain, speed box drive.
1—5' American, plain, motor driven.
5—5' Special, 2½" spindle, arm does not raise and lower, hand feed.
1—New 6' Fosdick, speed box drive, July delivery.

DRILLING MACHINES—HEAVY DUTY.

2—No. 26 Foote-Burt, 44" swing, 3½" capacity in solid steel.
3—No. 14 Colburn, 24" swing, capacity 2" in solid steel.

DRILLING MACHINES—MULTIPLE SPINDLE.

1—30C Baush 12-spindle, capacity 1¼" holes, 30" circle.
1—Gardam, 12-spindle, capacity ¾" holes, 14" square.
1—No. 5 Fox, 12-spindle, rectangular head 20" x 30", capacity 1" holes, tapping attachment, speed box drive.
1—14-spindle Baush, capacity 1" holes, 36" circle.

GEAR CUTTING MACHINES.

1—16" Bilgram Bevel Gear Generator.
1—12" G. & E. Gear Hobber.
1—12" Gleason Bevel Gear Planer.
1—15" Gleason Bevel Gear Planer.
1—20" Grant-Lees Gear Hobber.
1—No. 1 20" Schuchardt & Schutte Gear Hobber.
1—22" x 8" Gear Cutter for Spur and Bevel.
1—24" Fellows Gear Shaper.
1—24" x 8" G. & E. for spur and bevel.
1—26" x 10" Cincinnati, spur gears only.
1—No. 3 26" B. & S., spur gears only.
1—New 30" Flather, spur gears only.
3—36" Fellows Gear Shapers.
1—No. 4 36" B. & S., spur gears only.
1—50" x 11" G. & E., spur gears only.
1—96" Gleason, for spur and bevel gears.

GRINDERS—UNIVERSAL—FOR CUTTERS, DRILLS, REAMERS, ETC.

1—New Norton, No. 1.
1—New Wilmarth & Morman, style BX.
1—No. 1 Cincinnati.
1—New Walker No. 2, outfit K (capacity 9" x 26").
4—No. 190 Wells.

GRINDING MACHINES—CYLINDRICAL—PLAIN.

1—No. 11 (6 x 30") Brown & Sharpe.
1—6" x 48" Pratt & Whitney.
1—No. 16 (10" x 72") Brown & Sharpe.
1—New No. 12 (8" x 26") Brown & Sharpe.
6—12" x 24" Modern, self-contained.
6—12" x 36" Modern, self-contained, motor driven.
6—12" x 48" Modern, self-contained, motor driven.
1—10" x 50" Norton.
1—10" x 60" Landis.
1—16" x 66" Landis, with crank grinding attachment.
1—14" x 72" Queen City.
1—18" x 96" Brown & Sharpe.

GRINDING MACHINES—CYLINDRICAL—UNIVERSAL.

1—No. 1 Fraser, with surface grinding attachment.
1—No. 1½ (10" x 30") Landis.
1—No. 2 (12" x 30") Brown & Sharpe.
1—New No. 2 Bath.
1—No. 2½ (10" x 36") Bath.
1—10" x 42" Modern.
1—No. 3 (12" x 40") Brown & Sharpe.
1—12" x 42" Landis.

GRINDING MACHINES—INTERNAL.

1—No. 1½ Landis.
1—No. 75 Heald.
1—No. 6 (6" x 6") Rivett.

GRINDERS—CYLINDER.

1—No. 60 Heald, single pulley drive.
1—No. 27 Brown & Sharpe.

GRINDERS—DISC.

1—No. 14 Besley.
1—New No. 17 Gardner (Pattern Makers).
1—No. 41 Oliver (Pattern Makers).

GRINDING MACHINES—RING.

1—No. 200 Heald.

GRINDING MACHINES—EDGE.

1—No. 374 Safety Emery Wheel Co.

GRINDING MACHINES—SURFACE.

4—New No. 2 Reid (same as B. & S.).
1—No. 1 Diamond, cap. 12" x 12" x 24", automatic.
1—New No. 2 Wilmarth & Morman.
1—New No. 3 Wilmarth & Morman.
1—22" x 12" x 60" Springfield, planer type, automatic.

GRINDING MACHINES—DUPLEX.

1—No. 5 Bath suitable for grinding cylinders, pistons, piston rings, etc., 16" feed, swivel table, water pump.

GRINDING MACHINES—FACE.

1—Diamond Face Grinder, 4' travel, 14" wheels.

HAMMERS—POWER—FORGING.

1—40-lb. Bradley Helve.
1—150-lb. Bradley Helve upright.

HAMMERS—BOARD LIFT—DROP.

1—200-lb. (no name).
1—400-lb. Billings & Spencer.
1—400-lb. Toledo.
1—400-lb. Zeh & Hahemann.

HAMMERS—STEAM—FORGING.

1—New 600-lb. Bell.
1—New 3,000-lb. Bell, September delivery.

KEYSEATERS.

1—Mitts & Merrill motor driven.
2—No. 0 Mitts & Merrill.
1—No. 00 Baker Bros.
1—60" stroke Compton Knowles Broacher.

LATHES—ENGINE.

1—11" x 6' Bradford, taper attachment.
2—16" x 6' LeBlond, pan bed, quick-change gears, taper attachment.
1—16" x 6' LeBlond, quick-change gears.
1—New 17" x 8' National, taper attachment.
1—18" x 8' L. & S., geared head, taper.
1—New 19" x 8' LeBlond, heavy duty.
3—18" x 9' Chard.
9—18" x 8' American, geared head.
1—20" x 16' Greaves-Klusman, taper attachment.
3—22" x 10' Davis.
9—22" x 10' Putnam, oil pan, turrets.
4—24" x 10' Reed.
2—24" x 12' S. & B.
1—24" x 14' Lodge & Shipley, patent head.
4—24" x 14' American, quick-change.
1—24" x 24' Perkins.
3—New 26" x 12' Boye & Emes.
1—26" x 24' New Haven.
4—New 28" x 12' Boye & Emes.
1—28" x 18' S. & B.
5—New 30" x 14' Boye & Emes.
3—New 32" x 12' Fitchburg pattern.
1—36" x 15' Fifield.
2—New 36" x 18' Putnam, triple geared.
12—New 36" x 24' Putnam, triple geared.
1—25"-45" x 22' McCabe, double spindle.
1—71" x 20' Fifield, triple geared.

LATHES — MANUFACTURING — NOT SCREW CUTTING.

13—No. 3X Reed-Prentice, semi-automatic.
2—No. 2X Reed-Prentice, semi-automatic.
6—No. 11 Amalgamated, for machining and profiling 5" shells.
3—18" Reed Grooving and Undercutting.
3—No. 1X Reed-Prentice, semi-automatic.
5—20" x 10' Hindman, high duty.
18—3½" x 60" Fitchburg, Lo-swing.
60—14" x 6' Reed, Stud and Bolt.
5—16" x 8' Fairbanks-Morse, heavy duty.
22—18" x 8' Battle Creek, heavy duty.
5—20" x 8' Merschon.
12—21" x 8' LeBlond, quick-change with attachment for grooving and facing both ends of shells with air cylinders and mandrels for 5" shells.
70—New Simplex, 16" x 8'.

MILLING MACHINES—KNEE TYPE—UNIVERSAL.

2—New No. 1 Kempsmith.
1—No. 1½ Garvin.
1—No. 2A Kearney & Trecker, single pulley drive.
3—No. 2½ LeBlond, Sept. delivery.
2—No. 3H LeBlond, Sept. delivery.
1—No. 3 Cincinnati, single pulley drive, higher power, vertical attachment.

MILLING MACHINES—KNEE TYPE—PLAIN.

1—No. 14 Garvin.
1—No. 0 Pratt & Whitney.
1—No. 21 Garvin.
3—New No. 1 Rockford.
2—New No. 1 Kempsmith.
1—New No. 2 Rockford.
1—New No. 3 Kempsmith.
1—No. 3 LeBlond.
1—No. 3 Hendey Norton.
1—No. 4 Brown & Sharpe.

MILLING MACHINES—VERTICAL.

3—New Bristol, 10" x 28" table, 21" power feed.
1—New No. 4B Becker.
2—No. 5 Becker.

MILLING MACHINES—PLANER TYPE.

1—No. 1 Beaman & Smith, two vertical spindles, working surface of table 72" x 14".
1—No. 1 Beaman & Smith, combined vertical and horizontal, working surface of table 72" x 18".
1—Beaman & Smith Slab Miller and Shaft Keyseater, with vertical routing attachment, working surface of table 96" x 17".
2—Ingersoll Slab Millers, working surface of table 60" x 20".
2—No. 1 Beaman & Smith, vertical spindle, open side, working surface of table 120" x 24", removable housing on one side.
1—Ingersoll Single Spindle, side head, motor driven, table 96" x 30", cutter head 30" in diameter.

OPPORTUNITY

BECKONS YOU TO

WELLAND

The Growing Industrial Centre Offers Great Inducements to Manufacturers

Welland is an unrivalled point for the location of industrial enterprises of all kinds. It is a natural centre for the location of manufacturers and is conceded by the captains of industry to be blessed with a Chicago-like future.

Railroad Advantages

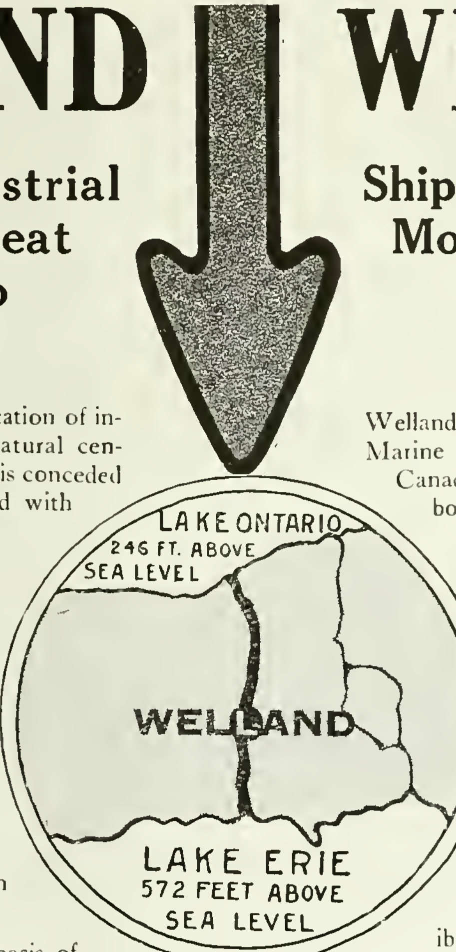
On account of close proximity to the border, Welland is in the Buffalo switching group and takes the Buffalo rate from the East and South and enjoys quick delivery on all raw material imported from the United States.

Seven Railroads

Grand Trunk — Michigan Central — Toronto, Hamilton & Buffalo — Canadian Northern — Pere Marquette — Canadian Pacific — Wabash.

Switches or spurs are constructed on the basis of of cost, the manufacturing firm paying the cost price and the railroads refunding a fixed sum for every car switched over the spur until the full amount is rebated. This rule prevails throughout the entire Dominion of Canada.

Rates from Welland to the North-West and Pacific Coast, all rail, are the same as from all other manufacturing points in Eastern Canada lying between the Detroit River and Montreal.



WELLAND

Ship Canal Will Carry More Vessels and Tonnage Than the Panama Canal

Welland is situated on the Welland Canal, the great Marine highway, between tide water and the Canadian North-West with daily freight service both ways.

The Canal carries boats of fourteen-foot draft, but work has now begun on canal enlargement to the amount of fifty-million dollars to provide for a twenty-five foot draft.

Distinct Advantages

In these days of keen competition water transportation has become an absolute necessity to manufacturers, and Welland holds the distinct position of being the only municipality in the entire Dominion of Canada, owning and operating its own municipal wharf, accessible by all shippers and steamboat lines alike, without charges of any kind.

Welland is a port of entry for all upper lake lines of steamers giving low rates and quick dispatch, the advantages of which are enormous.

Not even the World renouned Panama will carry the number of ships and same amount of tonnage as the Welland Canal.

CHEAPEST POWER IN CANADA

Welland Uses More Hydro Power Than Any Ontario City

Welland is the industrial hub of the Niagara Peninsula, where an unlimited amount of electric power is available and sold at competitive prices, owing to the numerous power companies represented there.

Every factory in Welland is driven by electric power supplied by the Ontario Power Co. of Niagara Falls, which is about twelve miles east of Welland, or from the Dominion Power Co. of De Cew Falls, which is about twelve miles north of Welland. The fact that we have competitive companies operating in this district gives us competitive prices on power. The average price per horse power per year for twenty-four hour service is about fifteen dollars. The price depends entirely upon the quantity of power used and the load factor. For ten hour service one class of meter will be installed and the power will be sold on a killowatt basis. Our present concerns pay an average of about three-quarters of a cent per killowatt hour. The large plants that use twenty-four hour power are securing a rate of about $13.50 per H.P. per annum.

Welland's Present Hydro Consumption is Over 83,000 H.P.

Welland's Pay Roll Grows Bigger Even in War Time

Welland has strong combination of advantages. Send for booklet

MacLean's Magazine
FOR JULY

The Smugglers were Caught

THE true and complete story of a huge smuggling conspiracy which robbed the Canadian and United States Customs Departments of hundreds of thousands of dollars, and which was finally exposed by a Canadian Customs officer, is well told in the July MACLEAN'S. The parties concerned settled by handing over a huge check to the Canadian Government and not a word of the story has ever before been in print. The man who writes the article, J. D. Ronald, was personally concerned in the investigation, and he tells the whole case from first to last, merely changing the names of some of the central figures. This is one of the most striking special features that MACLEAN'S has ever had.

Confederation
the dominant theme of July MACLEAN'S

THE Jubilee of Confederation has led the Editor to make the July MACLEAN'S retrospective and interpretive of Confederation in the character of its main contents—this to meet the certain need and desire of the Canadian people. Note the fine provision of special Confederation article and features:

"THE MEETING OF MACDONALD AND BROWN."
By C. W. Jefferys, a frontispiece painted for MACLEAN'S.

"THE STORY OF CONFEDERATION."
By Thomas Bertram. A colorful narrative of the bringing about of the union of provinces.

"FIFTY YEARS OF BUSINESS EXPANSION."
By W. A. Craick, covering all phases of business—banking, insurance, manufacturing, agriculture, transportation, etc.

"THE BUILDING OF THE C.P.R."
By C. H. Mackintosh, former Lieutenant-Governor of the North West Territories, and an ex-editor of the Ottawa Citizen.

"CONFEDERATION AND AFTERWARDS."
By Agnes C. Laut. An article on Confederation and the taking over of the North West Territories from the Hudson Bay Company.

Look for this symbolic cover design in three colors at book stores and news-stands. It is a fine bit of work, and worth preserving.

"SOME CANADIAN CONTRASTS."
By Frank Yeigh. A sketchy article showing some of the most picturesque ways in which Canada has advanced during the last fifteen years.

"THE DRAFT."
By A. C. Allenson. A story of the part which Canadians took in the American Civil War.

MESSAGES ON CONFEDERATION
appear from the Premiers of many of the Provinces of Canada.

Billy Sunday Contributes:

"WHAT I THINK OF CANADA."
A brief article in the crisp, epigrammatical style of the famous evangelist, illustrated by some of his most recent photographs taken in action in New York.

The Fiction Features:

"THE GUN BRAND."
By James B. Hendryx. An interesting instalment of this exciting serial.

"THE OUTLAW BOAR."
By Clark E. Locke. A short story.

"PUTTING IT OVER."
By Hastings Webling. A golf story.

"THE CAPTAIN OF THE SUSAN DREW."
By Jack London. The first instalment of a two-part story—one of the last that London wrote.

The Best Number of MACLEAN'S

THAT has ever been put out is this July issue. It will be bigger, the articles are **by long odds** stronger, the stories more entertaining, and the illustrations more varied. Stephen Leacock's "Sunshine in Mariposa" is continued in this issue; also the regular Departments, Records of Success, Review of Reviews, The Business Outlook, and Information for Investors.

At All News-Dealers 15c.

"Leather, Like Gold, Has No Substitute."

A Business Built on a Foundation of Truth and Merit

"To thine own self be true,
And it must follow as the night the day,
Thou canst not then be false to any man."—Shakespeare.

The Semi-Centennial of Canada's Confederation is a fitting time to exploit the unequalled growth achieved by one of Canada's foremost metal manufacturers.

Following Shakespeare's advice "To thine own self be true, etc.," the Canada Metal Co., from a very modest beginning in 1887 has developed into a Dominion-wide industry.

A STANDARD POLICY

No Metal ever leaves our factory which we are not conscientiously satisfied is of *A-1 Harris quality through and through.*

SCIENTIFICALLY PREPARED

Modern appliances for manufacturing and a well-equipped laboratory in charge of skilled metallurgical chemists put beyond the pale of chance any inconsistency in the high quality of our alloys. The policy of honest effort to maintain our meritorious products accounts for our 30 years of success.

Harris "Heavy Pressure" is the Leading Babbitt

And is known as the Babbitt Metal "without a fault." It is best for all general machinery bearings.

Harris Heavy Pressure is a meritorious achievement of Made-in-Canada products which will bear emphasis at this time.

There's a "Canada Metal" Babbitt for every purpose and they are all reliable. Write for complete list. And remember, we guarantee our Babbitt Metals to give excellent service.

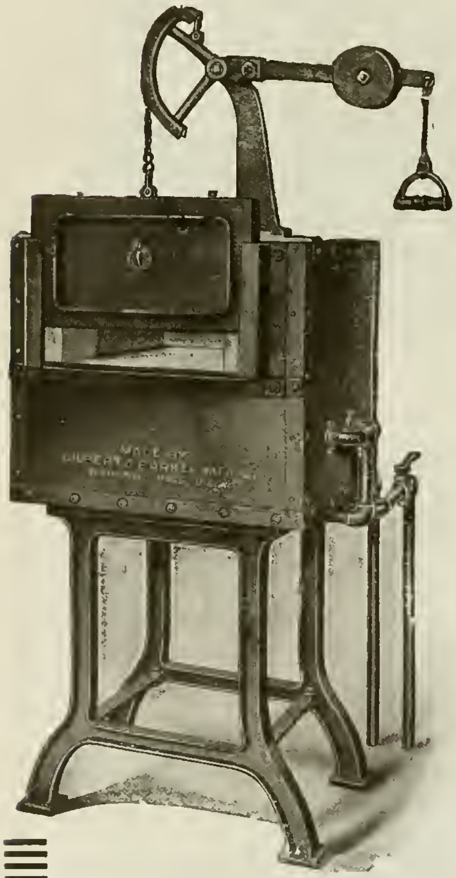
52 YEARS

TYPE E—4 FURNACE

WHERE EXPERIENCE COUNTS

There is something new to be learned about the intricate problem of heat treating every day. Over half a century's experience in burning liquid and gaseous fuels for treatment of metals has resulted in the present perfected type of G. & B. Furnaces.



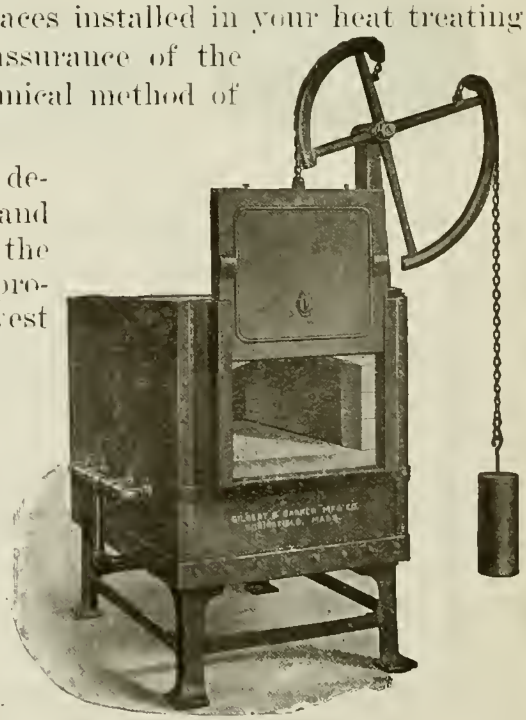
SMALL TYPE C FURNACE

These are the Days of Economy

Prices of labor and prices of raw material are making the cost of production hit the high spots. So economy is being shouted from the house tops! How about your heat treating? Are you getting the best results at minimum cost?

Gilbert and Barker furnaces installed in your heat treating department gives you assurance of the most efficient and economical method of production in existence.

G. & B. Furnaces are designed for convenience and ease of control, they give the right degree of heat, properly applied, with lowest possible fuel costs.



TYPE C—15

The benefit of long experience is at your service—Let us solve your heat treating problems for you. Drop a line now—delay may mean a good deal of lost money to you.

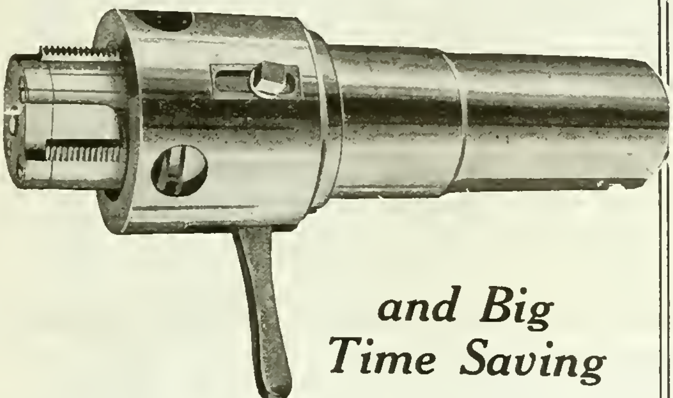
For Positive Accuracy—



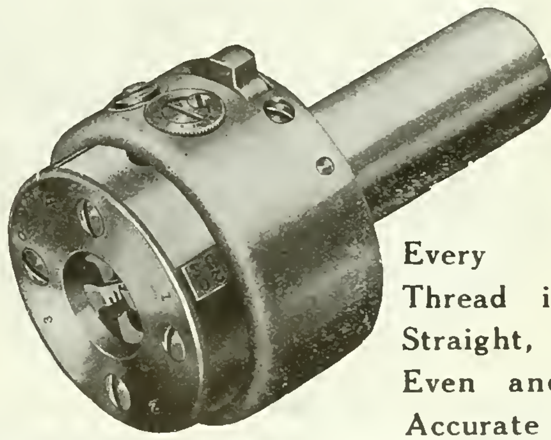
and Big Time Saving

"Victor" Collapsible Taps are simple in construction; the few parts can be made large and strong; the body is machine steel, and the chasers are high-speed; screw adjustment from front end makes it easy to maintain close accuracy; trip is automatic; reset by means of lever. The above features and others—make the "Victor" a time and money saver for severe service. It is being used by many shell manufacturers.

VICTOR Collapsible TAPS

Victor Tool Company

Waynesboro, Pa., U.S.A.



Every Thread is Straight, Even and Accurate

The Chasers in an *H & G Automatic, Self-Opening Die Head* are set and held in place by a steel cam. That cam once adjusted, locks; there is no stoppage or changing in size.

The quick release not only issues the cutting of the thread to a given point every time, but permits cutting right up to a shoulder when required.

Simple, Strong and Compact.

Our booklet tells more. *Drop a card for it.*

Eastern Machine Screw Corp.

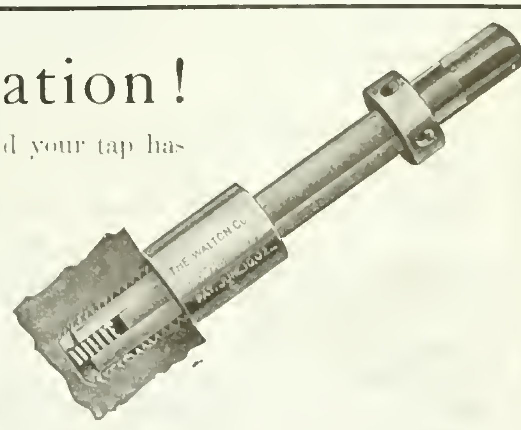
New Haven, Conn.

Here's a nasty situation!

A rush job when every minute counts, a snap and your tap has broken off close to the surface of the job.

HOW WILL YOU HANDLE IT?

Will you fuss around for half an hour or so trying to get hold of the broken piece?
Will you lose your temper and finish the job too late?
Not if you have a Walton Tap Extractor.
With this handy little device you can extract the broken piece in a jiffy and go on with your work.
The crucible steel fingers grip the flutes, a twist of your wrench and the piece is out.
Investigate this further. The Walton is reasonable in price.

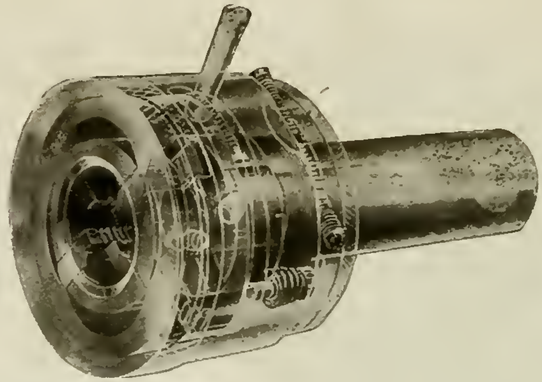


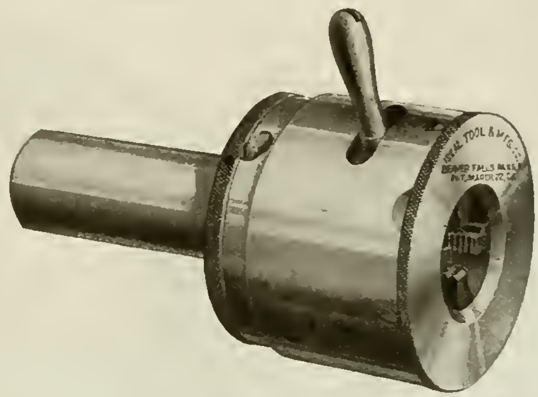
The Walton Company Hartford, Conn.

IDEAL DIES

Are big time savers. They make it possible for you to obtain clean, straight, absolutely accurate threads at a fast rate of production. Fineness of workmanship, quality of results and durability—all "IDEAL."

Try us.





The Ideal Self-Opening Die is simple in construction, has fewer parts than any similar tool; can be quickly and easily taken apart; cuts either right or left hand threads.

"Little David" Tools for Shipbuilders

In wooden shipbuilding the Wood Borer shown in the cut does splendid work. It is made in three sizes, boring holes from one to four inches in diameter.

"Little David" Riveters are widely used for driving wooden trenails, short drift bolts and spikes. They are also adapted for all operations in driving oakum, "horsing," etc.

Our CC-101 Drift Bolt Driver is a powerful and time-saving tool. With 100 lbs. air pressure, two men with this Driver can drive 1⅜" dia. bolts, 5 ft. long. 1-16" drift, full length in 25 seconds. It can be used in any position and at any angle.

For Steel Shipbuilding, our "Little David" Riveters, Chippers, Drills, Grinders, etc., will be found the most powerful and economical. Our bulletins will show you why.

We shall be glad to advise as to types and sizes of tools best suited to your work.

Your inquiries will be appreciated.

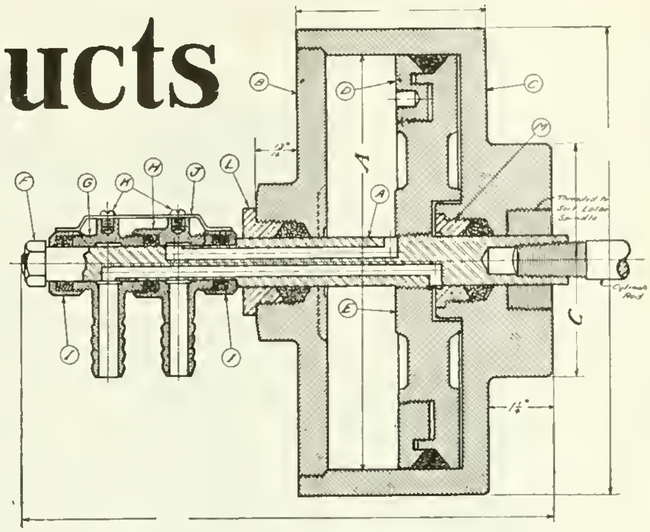
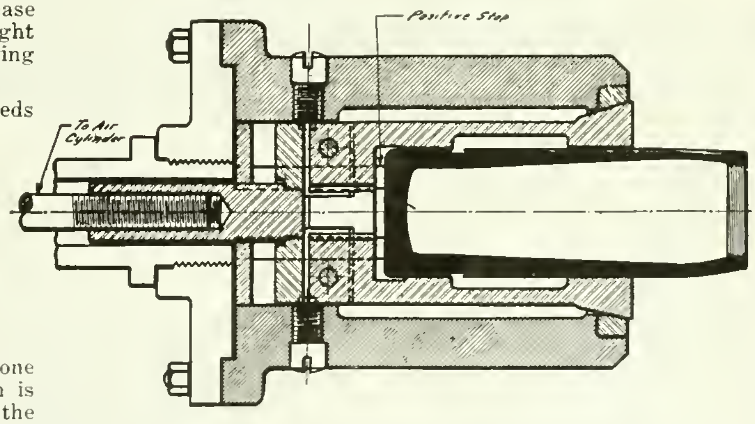
M.E.C. Products



are living up to the Industrial Slogan—

"Efficiency and Greater Production"

There is a well-justified demand for labor-saving equipment—and the demand will increase as the weeks go by, therefore—Now is the right time to place your orders for M.E.C. Labor-saving Equipment.



The M.E.C. Air Cylinder, for instance, speeds up production materially, improves its quality—and creates a greater manufacturing economy. That is why it is popular with every munition plant, automobile factory, gas engine builder, and wherever a greater and more economical production is the serious problem. The M.E.C. Air Cylinder is the very essence of simplicity.

In Style "D" shown herewith—an absolutely perfect metal to metal seat is effected because the head is screwed in as one solid piece. Adjusting packing ring or piston is only a few minutes' job—operator unscrews the head—gives the piston ring one or two turns—puts back and screws in the head in a second or two and he is ready for further operation—nothing could be simpler or quicker.

It is especially adapted for special chucks or fixtures requiring operation in either direction.

M.E.C. Air Operated Hinged Collet Chucks Are Recommended By The Leading Chuck Users Everywhere.

They grip uniformly and instantly and do not mar the work in the slightest degree. It does away with the wrench and all its attending lost motion. A turn of the air valve operates jaws. It has the record of increasing output from 50 to 90 per cent. Get our catalog on full line of M.E.C. Labor-Saving Devices: two-jaw and three-jaw chucks, air operated expanding mandrels and collapsible taps. Fill in coupon and send to-day.

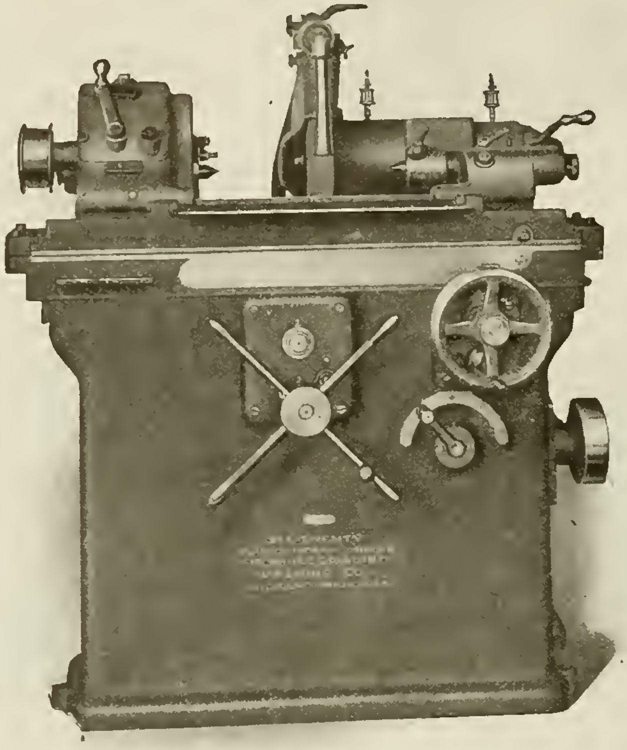
Your Grinding Concerns You Only



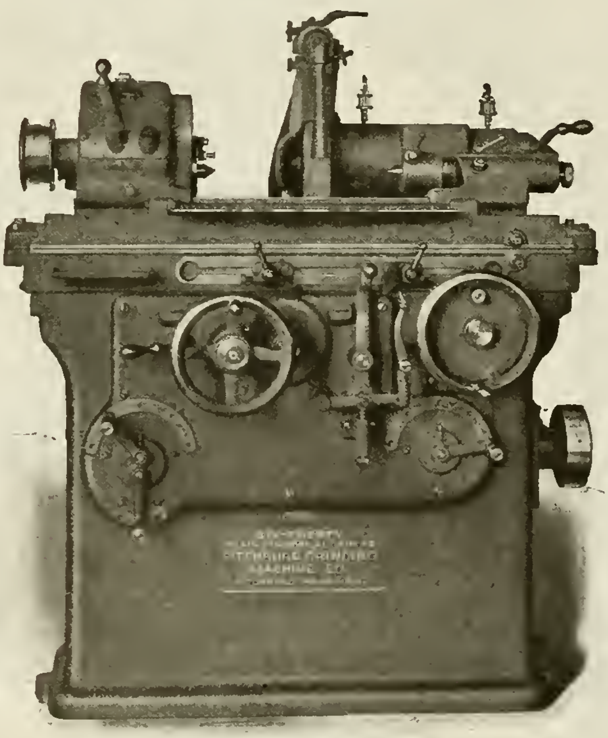
MODEL B

Examples of the wonderful results obtained by our users would not benefit you. Your difficulties may be entirely different, and it is these "different" problems that the Fitchburg shows to advantage.

Model "B" shown here is thoroughly efficient—and the large pilot wheel on the traverse table is especially convenient and allows for greater speed. It is made for grinding short, cylindrical pieces. Your work may not be of this nature.

Write us and secure our co-operation.

If Quality is Concerned—so is "Fitchburg"



MODEL A

Both Models are equipped for straight or taper shaft grinding and the difference in the machine is that the Model A is arranged with power feeds and the Model B is hand operated.

Constructed on the unit system, each unit may easily be removed from the machines. Lubricating features reduce wear and friction to a minimum.

Specifications and full information gladly furnished.

Diameter of Rear Bearing	1¼"
Length of Spindle	15"
Hole through Spindle	1¼"
Draw-in Chuck Cap	1" maximum

From the above specifications you will observe that it is ideally designed for ordinary or specially fine work. Study the illustration and then write us for further information.

Cataract Tool Post Lathe

An ideal machine for fine work. Especially adapted for optical work or any series of work where operations such as turning, boring and recessing, also internal and external threading, must be done in one setting.

Six tools in turret independently adjustable.

Additional tailstock, turret or other standard attachments allowable.

Will take round stock ½", ¾" 1", 1⅜" and 1 11-16". In ordering kindly mention chuck capacity desired.

One horse-power required. Supplied with or without motor drive.

Catalogue No. 15 is ready to mail to you to-day. Write for it to-day.

HINTS TO BUYERS

Eliminate Danger

Accidents break down the efficiency of your organization, lead to legal troubles, loss of time and money.

TRADE MARK
BRISTO
REG. U. S. PAT. OFFICE

SAFETY SET SCREWS

insure safety. They also protect themselves because of their patented construction. The dove-tailed design of wrench and screw contracts the metal under pressure. The harder you twist the wrench the more the metal of the screw is compressed.

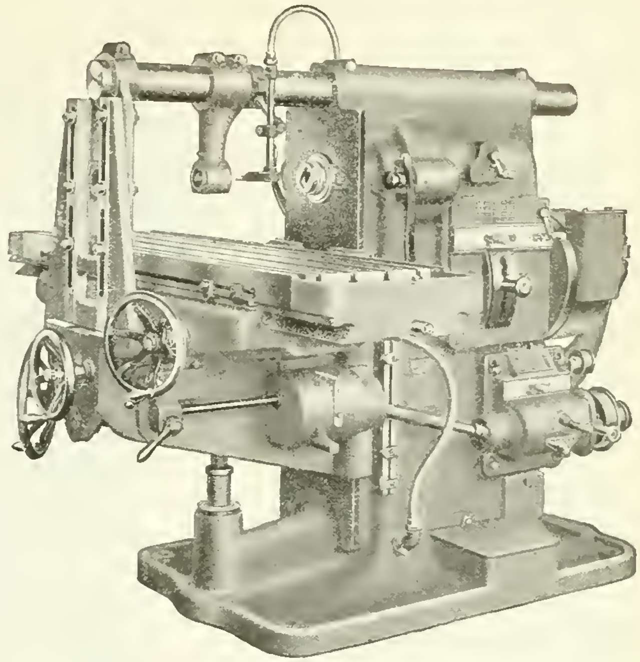
"ACCURACY—The First Requirement of Every Brown & Sharpe Product"

We Could Build Them Quicker But *Not* Better



We could build our milling machines faster at the sacrifice of Brown & Sharpe standards. They would look very much the same even to the smaller details—but

BROWN & SHARPE MACHINES MUST BE ACCURATE

and to get permanent accuracy, careful workmanship must enter into every important step in their manufacture. The great care used, however, does not mean that unnecessary time is consumed in building the parts or assembling them—just long enough to insure maintenance of Brown & Sharpe standards for accuracy that have been world-known for years.

You will find satisfaction and profit in an installation of

Brown & Sharpe Heavy Service Milling Machines

Brown & Sharpe Mfg. Co., Providence, R.I., U.S.A.

Canadian Representative:—CANADIAN FAIRBANKS-MORSE CO., LIMITED

Toronto Montreal Vancouver Winnipeg Calgary St. John Saskatoon

---

Cuts Costs Increases Production — *it is a Rockford Machine*

This powerful machine is made to drive high-speed drills up to 3" diameter, for drilling and boring tools up to 8" in diameter for boring out cored holes in cast iron.

It has a lateral and vertical adjustment of the head that permits the spindle to operate anywhere on a surface 18" high by 36" wide.

Sufficiently accurate for the finest jig work.

Investigate now. Write us for full particulars and specifications.

Used for the finest of Jig Work.

Canadian Shipbuilders

Ask us for a circular of this machine built specially for your needs.

Built absolutely on honor and the most up-to-date machine of its kind made to-day.

It will appeal to the small shop as well as to the large. The price is right and it will mean for you a tremendous saving in labor as well as a wonderful increase in production.

For good delivery, write us at once, as we have sold considerable already.

WHITTAKER'S BOOKS

A Complete Catalogue of Engineering Works published by us will be sent post free on application.

JUDGE.—High Speed Internal Combustion Engines.. By A. W. Judge. A.R.C.S., A.M.I.A.E. 360 pages. Medium 8vo. With 208 Illustrations, and 38 Tables. 15s. net (postage 6d.; abroad 1s.).

——— **The Properties of Aerofoils and Resistance of Aerodynamic Bodies.** 300 pp. Medium 8vo. Cloth. With 150 Figures. 15s. net (postage 6d.; abroad 8d.).

DOVER.—Electric Traction; A Treatise on the Application of Electric Power to Electric Traction on Railways and Tramways. By A. T. Dover, A.M.I.E.E., Assoc. Amer. I.E.E., Lecturer in Electric Traction at the Battersea Polytechnique, London. With 518 Illustrations, 33 Tables, 5 Folding Plates. 688+xx pp. Medium 8vo., cloth, 18s. net (postage 7d., abroad 1s.).

DOVER.—Power Wiring Diagrams: A Handbook of Connection Diagrams of Control and Protective Systems for Industrial C.C. and A.C. Machines and Apparatus. With 254 Illustrations. Pocket size (6½" x 4"). F'cap 8vo., cloth, 6s. net. (Rounded edges).

PULL.—Modern Milling. A Practical Manual on Milling Machines, Milling Accessories, and Milling Operations, for the use of Engineers, Milling Operators, Practical Mechanics and Engineering Students. By Ernest Pull, A.M.I. Mech.E., M.I.Mar.E. With 188 Illustrations and many Tables. Demy 8vo., cloth, 7s. 6d. net (postage 5d.; abroad 6d.).

MAYCOCK.—Electric Wiring, Fittings, Switches and Lamps (Circuits). A Practical Book for Electric Light Engineers and Contractors, Consulting Engineers, Architects, Builders, Wiremen, and Students. Fifth Edition, Revised. With 620 Illustrations. Crown 8vo. 7s. d. net (postage 6d.; abroad 10d.).

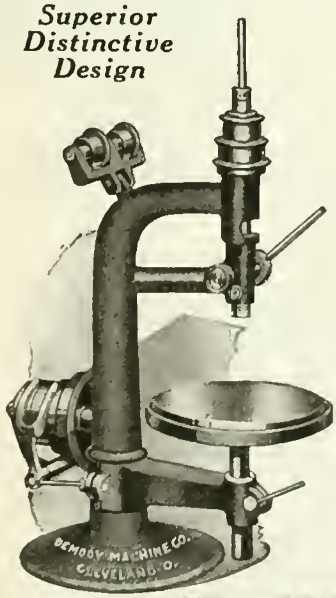
WHITTAKER & COMPANY

2, White Hart Street, Paternoster Square

LONDON, E.C. 4, ENGLAND

A Good, Hard and Fast Worker

Superior Distinctive Design



The
DE MOOY
IMPROVED SENSITIVE
DRILLS

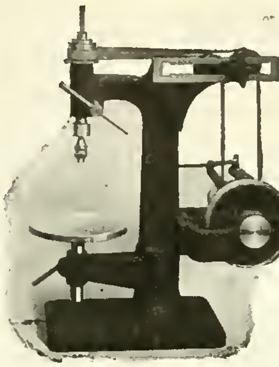
are built in two sizes; No. 1 has capacity from 0 to 5-16"; No. 2 from 0 to ½"; No. 2 is built in two types, either as Bench or Floor drill.

The machines are built sturdy; compact; convenient; economical and dependable for small accurate drilling.

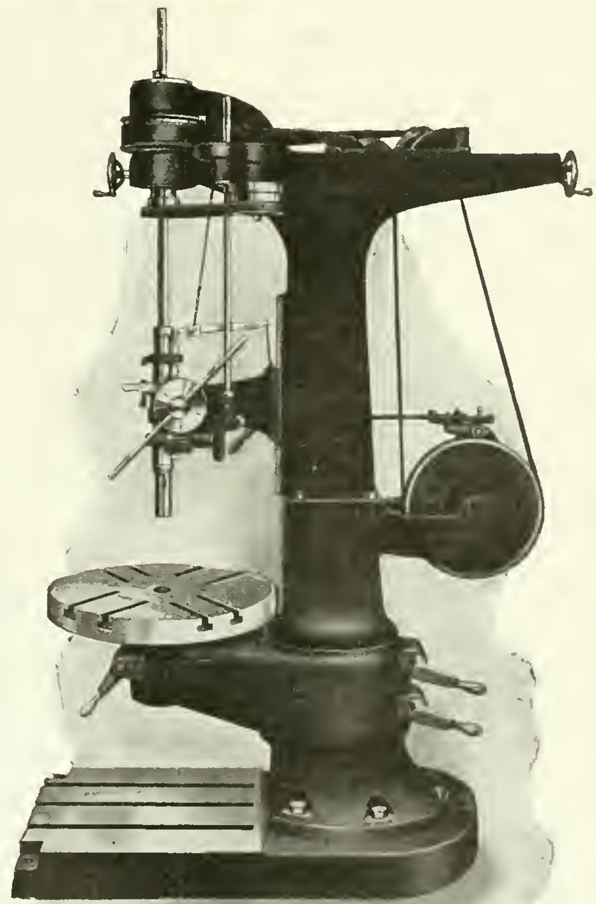
Write for specifications.

The De Mooy Machine Co.

CLEVELAND, OHIO



From the
SMALLEST
to the
LARGEST
in Ball Bearing Sensitive Drilling Machines



WHATEVER YOUR REQUIREMENTS

as to size, if you want to get the machine most suitable to your work, get the

Avey

The widest line in sizes,—the greatest variety in styles:—higher speeds, together with extreme simplicity and convenience, enable you to specialize to best advantage.

HERCULES

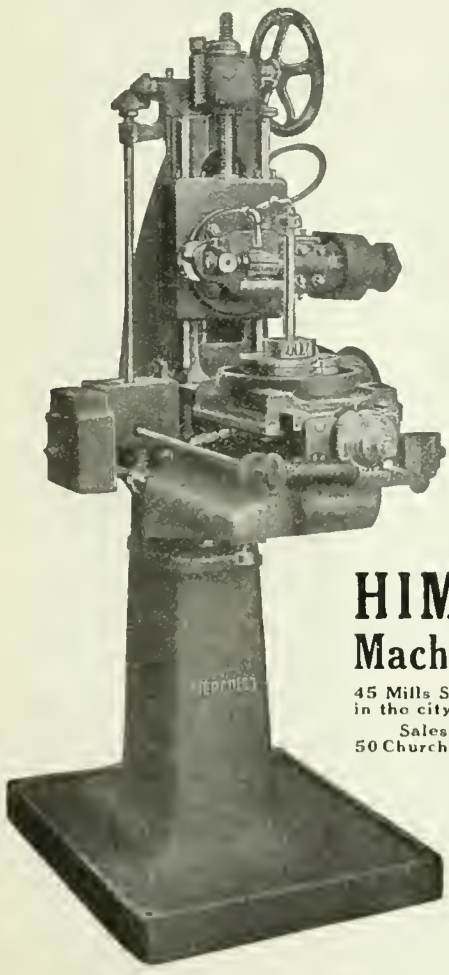
For Rapid and Accurate Cutting of Small Gears

such as those used in typewriters, meters, adding machines, magnetos, speedometers, etc., use

The New Hercules Gear Hobber

Construction throughout is heavy and all parts are well supported to prevent vibration and assure long service. The drive is simple, powerful and smooth; all movements are gear operated and no chains are used in transmission.

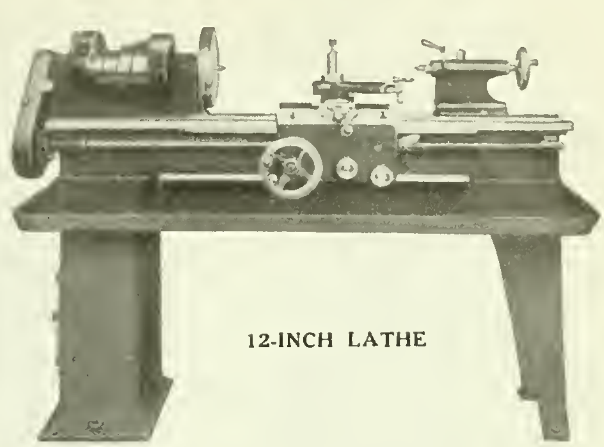
Spur, worm, or spiral gears up to 8-inch diameter and 8-inch face can be handled at maximum speed—steel gears up to 10 pitch, cast iron gears up to 8 pitch—on the No. 1 machine.



HIMOFF
Machine Co.

45 Mills Street, Astoria in the city of New York
Sales Offices:
50 Church St., New York

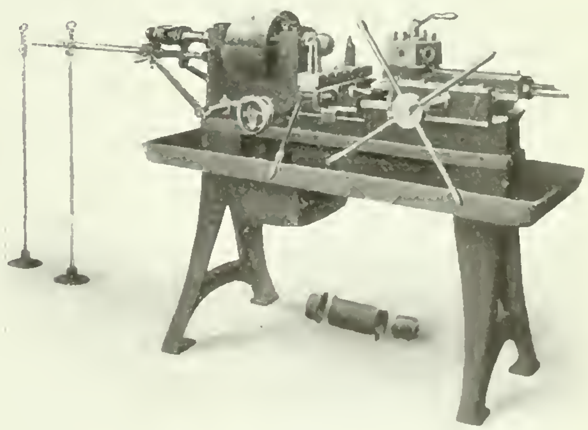
HERCULES



12-INCH LATHE

HERCULES LATHES

It isn't what you do—it's how you do it. Any lathe may do your work, but how will it do it? That is the basis of the Himoff Lathes. They have "Herculean" strength and are strictly modern in design. Rigidity and accuracy guaranteed. Detailed specifications on request.



Hercules Screw Machines

are built with $\frac{5}{8}$-inch, 1-inch and $1\frac{1}{2}$-inch chuck capacities. They are rugged, powerful, handy machines; capable of continuous high production over a wide range of work.

Himoff Machine Company

45 Mills Street
Astoria, City of New York, N.Y.
